Dear Sir or Madam,

Please find enclosed a disk containing robust summaries and a proposed test plan for the following intermediate production stream:

CAS# 63890-96-5 Chlorinated C3 Stream

The information is being submitted for the HPV Challenge Program, AR-201, on behalf of The Dow Chemical Company, and the files are provided in Microsoft® Word format.

Should you need further information regarding the submission, please contact me at any time. You may also address comments or concerns to Dr. William Stott of The Dow Chemical Company at (989)-636-8203.

Kind Regards,

Carrie E. Houtman

TEST PLAN

For

C3 Chlorinated Hydrocarbon Stream (CASRN 63890-96-5)

CASRN:	63890-96-5
Sponsor	The Dow Chemical Company Midland, Michigan
Date of Submission:	14 December 2004
Date of last Update:	10 December 2004

Test Plan for C3 Chlorinated Hydrocarbon Stream
(CASRN 63890-96-5)

I. SURROGATE JUSTIFICATION

CAS 63890-96-5 C3 Chlorinated Hydrocarbon Stream consists of several chlorinated 3-carbon chemicals which are produced as intermediate streams from several manufacturing product lines. Though somewhat variable, the largest volume components of CAS 63890-96-5 are 1,2-Dichloropropane (approximately 65%), Trichloropropene (8%), and 2-Chloropropene (6.5%) The remaining CAS 63890-96-5 C3 Chlorinated Hydrocarbon Stream is composed of a number of chlorinated propenes with no other single component present at more than a 5% of the total stream.

PDC will be used as a “surrogate” chemical for defining the toxicity of CAS 63890-96-5 C3 Chlorinated Hydrocarbon Stream as part of the HPV program based upon its high volume percent of the stream and the wealth of mammalian and environmental toxicity. PDC (65%), Trichloropropene (8%) and 2-Chloropropene (6.5%) all exhibit remarkably similar toxicity profiles (Bingham, 2001). While the acute oral and dermal LC₅₀'s of Trichloropropene and 2-Chloropropene are lower than those of PDC, toxicity via inhalation is very similar. The three components show very comparable subchronic NOAEL's, are all considered to be non-carcinogenic in *in vivo* testing, and all three have mixed or positive mutagenicity findings. They are similarly all considered to be non-teratogenic, although there were findings of mild delays in ossification in the fetuses at comparable dose levels. Based on the consistent toxicological profiles of the three compounds most abundant in the stream, it is reasonable to identify PDC as the surrogate for the stream.

Significantly, PDC has also been evaluated previously as part of the OECD SIDS program (<http://www.oecd.org>). It was judged to be “of low priority for further work” at SIAM 17 (November 2003) indicating the adequacy of its database for coverage of OECD SIDS endpoints. Information presented in the present HPV Test Plan and related IUCLID Robust Study Summaries were drawn heavily from the complimentary OECD SIDS documentation.

II IDENTITY

A. Identification of the Substance

CAS Number:	78-87-5
IUPAC Name:	1,2-Dichloropropane
Molecular Formula:	C ₃ H ₆ Cl ₂
Molecular Weight:	201.91
Synonyms:	PDC, Propylene Dichloride

The compound is a colorless liquid in the pure or neat state. Because of its structure, PDC has a high vapor pressure, and high partition coefficient (log K_{ow}). MacKay Level III fugacity modelling predicts that the substance will partition predominately to air.

B. Purity/Impurities/Additives

The compound is sold in its pure form.

C. Physico-Chemical properties**Table 1** Summary of physico-chemical properties

Property	Value
Physical state	colorless liquid
Melting point	-70 °C
Boiling point	95-96 ° C
Vapour pressure	66.2 hPa at 20° C
Water solubility	2800 mg/m ³ at 25° C
Partition coefficient n-octanol/water (log value)	2.0

III DEVELOPMENT OF ROBUST SUMMARIES AND STUDY SCORING CRITERIA

The Dow Chemical Company has chosen to use the IUCLID (International Uniform Chemical Information Database) format for preparation of robust summaries for the HPV program. Because many of the fields in the IUCLID database program are outside the scope of the HPV program, these fields are typically left blank in the IUCLID robust summary. Scoring of studies from company files or from the literature for reliability to fulfill the testing requirement for each endpoint used a system similar to that published by Klimisch *et al.* (1997). Studies were given a score of “1” if the data could be considered valid without restriction based on the completeness of the protocol and adequate details in reporting. Studies were given a score of “2” if the data and study design could be considered scientifically valid to address the endpoint but with restrictions due to lack of various technical or reporting details or deviations from current OECD guidelines. Studies were given a score of “3” if their conduct was not acceptable and “4” if there wasn’t enough information present to assign a reliability rating. However, a

study receiving a score of “4” could provide supplementary information that could be used to address the endpoint in a weight of evidence evaluation in the absence of other data.

IV TEST ENDPOINT RESULTS

Evaluation of the data for PDC leads to the conclusion that the quantity of data to adequately represent the toxicological and ecological profile of CAS 63890-96-5 C3 Chlorinated Hydrocarbon Stream. A summary of the data on each of the HPV/SIDS endpoints for the compound follows.

A. Physical Chemistry

Melting Point

IUCLID 2.1: PDC is a liquid in the neat or pure state with a melting point of -100.4°C (Mackay, 1993). The melting point is well-documented in peer-reviewed literature and databases. **No additional testing is required.**

Boiling Point

IUCLID 2.2: The boiling point for PDC is well-documented (Mackay, 1993). **No additional testing is required.**

Vapor Pressure

IUCLID 2.4: The vapor pressure for PDC has been well-documented in published literature and chemical handbooks. The experimental value is 66.2 hPa at 25°C (Mackay, 1993). **No additional testing is required.**

Partition Coefficient

IUCLID 2.5: Partition coefficient is well-documented (Mackay, 1993) for PDC. **No additional testing is required.**

Water Solubility

IUCLID 2.6.1: Measured data indicates that PDC is soluble in water. Measured aqueous solubilities of 2800 mg/m³ is reported. (Mackay, 1993) The low log K_{ow} also supports the reported data for water solubility. Sufficient data exist for this endpoint to characterize water solubility for the compounds. **No additional testing is required**

B. Environmental Fate**Photodegradation**

IUCLID 3.1.1: The compound does not absorb light >290 nm, and therefore direct photolysis is not possible (Howard, 1990). Vapour phase photolysis under simulated sunlight did not occur after prolonged exposure (period not stated). Experimental determination of its rate of reaction with hydroxyl radicals gave a half-life of >23 days. A computer estimate of its half-life due to H-atom abstraction by hydroxyl radical yields a calculated half-life of 7.12 days. **No additional testing is required**

Stability in Water (Hydrolysis)

IUCLID 3.1.2: PDC does not possess a molecular structure that contains functional groups subject to rapid hydrolysis under neutral ambient conditions; the ~~life~~ half-life at pH 7 is estimated to be 15. 8 years (Mackay, 1993).

Hydrolysis produces 1-Chlor-2-propanol and HCl. This testing endpoint is well characterized. **No additional testing is required.**

Environmental Transport

IUCLID 3.3.1: Based upon the EPIWIN Level III Fugacity Model, PDC is expected to stay primarily in air, as is shown in the following table. The assumption is for emissions to air only (according to U.S. EPA TRI Database, >99.9% of reported PDC emissions are to the atmosphere).

Predicted Environmental Partitioning of PDC

Compartment	Level I	Level III
Air	98.02	98.85
Water	1.82	0.93
Soil	0.16	0.21
Biota	<0.01	ND
Sediment	ND	<0.01

The EPIWIN Level I Fugacity Model results predict a similar fate. Advection in air accounts for 88.6%, and reaction in air for 11.2%, of the removal rate.

Advection and reaction in water, sediment, and soil account for 0.2% of removal rate. Although the values obtained using this model should not be regarded as quantitative, the model results are consistent with the properties of the compound.

No additional testing is required.

Biodegradation

IUCLID 3.5: Biodegradation is the conversion of a chemical by microorganisms in the environment into its simpler components and ultimately to carbon dioxide and its other constituent molecules. Chemicals are classified as readily biodegradable by the Organization for Economic Development (OECD) guidelines if there is a 70% degradation of dissolved organic carbon within a 10-day period during a typical 28-day laboratory protocol.

No biodegradation of PDC was detected when PDC (150 mg/l) was incubated aerobically with municipal activated sludge (1,000 mg/l mixed liquor suspended solids) for 28 days in an OECD 302B (modified EMPA Zahn-Wellens test), conducted according to GLP requirements (2002). However, there are published examples of acclimated municipal and other systems where PDC does undergo biodegradation, including addition of co-factors (acetate and methanol), and enrichment of cultures (Hauck and Hegemann, 1999; Hardy *et al.*, 1999). It is unknown if such conditions exist and if biodegradation occurs in the environment. A hydrolysis constant of 5.0×10^{-6} per hours (pH 7-9, 25° C) with a calculated half-life of 15.8 yr has been derived for water (MacKay *et al.*, 1993). These data indicate that there is sufficient information on the biodegradation potential of PDC. **No additional testing is required.**

C. Ecotoxicity

Toxicity to Fish

IUCLID 4.1: Consistent results were obtained from the fish toxicity studies of Walbridge *et al.* (1983) and Benoit *et al.* (1982) that demonstrate that PDC is of low acute toxicity towards freshwater fish (LC₅₀ ~140 mg/l). Although these studies pre-date current testing guidelines, they included analytical confirmation of achieved exposure concentrations which increases confidence in the reliability of the results obtained. In addition to the above, chronic aquatic toxicity data are available from a fish early life-stage (ELS). In the ELS test, a chronic NOEC of 6 mg/l was obtained for growth, and a chronic NOEC of 11 mg/l for survival, when *Pimephales promelas* was exposed to PDC for 28 days under flow-through conditions (Benoit *et al.*, 1982). The study included analytical verification of exposure concentration. **No additional testing is required.**

Aquatic Invertebrates

IUCLID 4.2: In a modern GLP-compliant guideline study using flow-through conditions and analytical confirmation of achieved concentration, Boeri (1988) obtained a 48 hr EC₅₀ of 55.9 mg/l for immobilization of *Daphnia magna*. The chronic invertebrate test, involving *Daphnia magna* (Boeri, 1988), was a GLP-compliant guideline investigation with analytical confirmation of exposure concentration. This returned a 21 day NOEC for effects on reproduction of 8.3 mg/l. Results from a 28 day study using the marine invertebrate *Mysidopsis bahia* (Ward *et al.*, 1989) gave a chronic NOEC of 4.1 mg/l for effects on mortality, reproduction and growth. The study was a GLP-compliant guideline investigation performed under flow-through conditions, with analytical

confirmation of achieved exposure concentration. **No additional testing is required.**

Aquatic Plants

IUCLID 4.3: Information on the acute toxicity of 1,2-dichloropropane on the salt-water algae *Skeletonema costatum* is available from Hughes (1988). This is a modern, GLP-compliant static guideline test, however GC analysis revealed variable losses of test substance from the screw-capped test vessels over the course of the study. As a result, no direct calculation of the EC₅₀ was possible. In recognition of this, Woodburn (2002a) used a time-weighted average AUC method (based on the measured dissipation rate of PDC from the test vessels) to calculate the no-effect concentration for this algal species. A NOEC_{120 hr} of 7.4 mg/l was thus obtained. In addition, Woodburn (2002b) calculated the percentage biomass inhibition and inhibition of growth rate over 72 hr based upon time-weighted average exposure concentration, and derived EC₅₀ values of 16.3 mg/l and 14.7 mg/l, respectively. De Groot (2002) also re-analyzed the original data from Hughes (1988) using linear interpolation after log transformation of the results obtained over the first 3 days of the study. This approach returned 72-hr EC₅₀ values of 15.1 and 15.8 mg/l for biomass and growth inhibition, respectively, and a 72-hr NOEC of 8.9 mg/l. Overall the data obtained by re-analysis of Hughes (1988) supports a 120-hr algal NOEC in the range 7.4-8.9 mg/l, with 72-hr EC₅₀ values of 15.1-16.3 mg/l for biomass inhibition and 14.7-15.8 mg/l for growth inhibition. **No additional testing is required.**

D. Toxicological Data

Acute Oral, Inhalation, and Dermal Toxicity

IUCLID 5.1.1-5.1.3 A number of studies are available which describe the acute toxicity of 1,2-dichloropropane in animals (summarized in the following table).

Although pre-dating modern guidelines and GLP, the results indicate that PDC is of relatively low inherent toxicity in animals after ingestion, skin contact, or inhalation. Given the high vapor pressure of 1,2-dichloropropane, inhalation exposure appears the most relevant route while rapid evaporation from skin would be expected to minimize any potential for local or systemic effects following dermal contact.

Summary of acute toxicity data for 1,2-dichloropropane

Endpoint	Species (details)	Result	Reference
Oral	Rat (Wistar)	2200 mg/kg bw	Smyth <i>et al.</i> , 1962; 1969
Inhalation LC ₅₀	Rat (4 hr)	2000 ppm 9.4 mg/l	Carpenter <i>et al.</i> , 1949; Smyth <i>et al.</i> , 1962
	Rat (7 hr)	> 2200 ppm > 10.3 mg/l	Highman and Heppel, 1946
	Guinea pig (7 hr)	> 2200 ppm > 10.3 mg/l	Highman and Heppel, 1946
Dermal LD ₅₀	Rabbit (occluded, 24 hr)	10,100 mg/kg bw	Smyth <i>et al.</i> , 1962; 1969

In contrast to the acute animal data, human case-reports suggest that the liver and red blood cells may be adversely affected following over-exposure by ingestion (Larcan *et al.*, 1977; Thorel *et al.*, 1986; Di Nucci *et al.*, 1988; Lucantoni *et al.*, 1992), inhalation (Pozzi *et al.*, 1985) or after prolonged, combined dermal and inhalative exposure (Fiaccadori *et al.*, 2003). Although quantitative exposure information is missing from many of these studies, and exposure to PDC is inferred rather than supported by analysis of the products involved, liver damage (hepatocellular necrosis, fibrosis, hypertension), increased serum transaminases,

haemolytic anaemia and intravascular coagulation were present reportedly in the subjects to varying extents. In two instances the subjects died after apparently ingesting 50-180 ml of industrial cleaning products (Larcan *et al.*, 1977; Di Nucci *et al.*, 1988) however the doses received by the remaining cases is not known. As a result of these findings, PDC is considered harmful by ingestion or inhalation.

No additional testing is required.

Irritation and Sensitization

IUCLID 5.2.1-5.3: Results from a GLP guideline skin irritation study (minimal redness and slight oedema), indicate that PDC is slightly irritating to skin (BASF, 1982). An early eye irritation study (BASF, 1965) reported marked redness, oedema and slight opacity 24 hr after instillation of 0.05 ml PDC into the conjunctival sac of a single rabbit. These effects were fully reversed after 8 days (no interim results available), and indicate that PDC is irritating to the eye.

Case reports provide equivocal evidence that PCD may cause allergic skin conditions after uncontrolled exposure in individuals with pre-existing dermatitis. In one study, 10 workers exposed to industrial preparations containing 10-40% PDC under conditions of poor occupational hygiene (hand cleaning using these products) exhibited an allergic response after patch testing with PDC with a threshold level of 2% (Baruffini *et al.*, 1989). However, all subjects suffered from pre-existing irritant skin-lesion and hand dermatitis that quickly resolved after cessation of exposure. In another brief report (Grzywa and Rudzki, 1981), two female workers with recurrent dermatitis responded to patch testing with 1% PDC as well as other substances present in the workplace. In contrast, results from an OECD 429 guideline mouse local lymph node assay (Woolhiser *et al.*, 2003) found no stimulation of lymphocyte proliferation in auricular lymph nodes

from mice treated with up to 80% PDC demonstrating that it was not a sensitiser under the conditions of this test. This lack of allergic potential in the mouse is consistent with structural considerations which provide no evidence of chemical alerts (reactive groups) that would indicate a potential to act as a sensitizer. In conclusion, based on the available data, PDC is considered to provide only equivocal evidence of an ability to cause skin allergy. **No additional testing is required.**

Repeated-Dose Toxicity

IUCLID 5.4: The oral repeat dose toxicity of PDC has been investigated extensively by NTP (1986) in a series of GLP-compliant studies using male and female F344 rats and B6C3F1 mice. Key aspects of the design of these studies, along with the main findings, are summarized in the following table. The results indicate that the liver is a target organ after gavage administration, with a chronic NOAEL of 125 mg/kg bw/day in female rats (males unaffected) and a chronic LOAEL of 125 mg/kg bw/day in male mice (females unaffected). Acanthosis of the stomach (indicative of persistent local irritation) was noted in mice (rats unaffected) with a chronic NOEL of 125 mg/kg bw/d in males and a chronic LOEL of 125 mg/kg bw/d in females. Body weight was decreased 14-24% in rats (chronic NOEL_{males} = 62 mg/kg bw/d, chronic NOEL_{females} = 125 mg/kg bw/d) whereas mice were unaffected (chronic NOEL = 250 mg/kg bw/d, both sexes). The overall NOAEL values following chronic administration of PDC were 62 and 125 mg/kg bw/d for male and female rats respectively. No NOAEL was derived for mice of either sex, so the LOAEL was 125 mg/kg bw/d.

The neurological consequences of repeated oral exposure to PDC have been investigated in F344 rats (n = 15/sex/group) given 0 (corn oil), 20, 65 or 200

mg/kg bw/day for 13 weeks by gavage (Johnson and Gorzinski, 1988). The study followed U.S. E.P.A. guidelines and was conducted to the standards of GLP. Prior to treatment, and at monthly intervals during the study, all animals were assessed for a number of endpoints including functional observational battery, hindlimb grip strength, and motor activity. After a 13-week treatment, 4 rats/sex/dose were randomly selected for terminal examination (including histopathological examination of brain, spinal cord and nerve) while the remainder were retained (no further treatment) for a 9 week recovery period. Transient clinical signs (lacrimation, blinking, decreased spontaneous motor activity) were reported on days 3-4 of treatment, and body weight was slightly decreased at week 13 in both sexes. There were no effects attributable to PDC in the functional observational battery, grip strength, or motor activity. Results from the gross and microscopic examination of the brain and nervous system revealed no treatment-related lesions. Overall, apart from a minor effect on body weight ($\text{NOAEL}_{\text{males}} = 20 \text{ mg/kg bw/day}$; $\text{NOAEL}_{\text{females}} = 65 \text{ mg/kg bw/day}$), no adverse structural or functional neurological consequences were apparent in rats following 13 weeks gavage administration of PDC at doses up to 200 mg/kg bw/day. The effects of repeated (13 week) inhalation exposure to PDC were investigated in rats, mice, and rabbits (Nitschke *et al.*, 1988). This GLP compliant study evaluated macroscopic and microscopic effects following exposures to 15, 50, and 150 ppm for rats and mice and 150, 500, and 1000 ppm in rabbits. Nasal respiratory changes, considered site-of-contact effects, were identified in rats, and slight reductions in body weight were also reported (NOEL of 15 ppm for both). No effects whatsoever were identified in mice (NOEL of 150 ppm). Results from rabbits demonstrated slight changes in red blood cell parameters, which were

indicative of a macrocytic normochromic, regenerative anemia (LOEL of 150 ppm for males; NOEL of 150 ppm for females).

Overall, results from repeat dose studies indicate that the liver is a target organ in rodents with a chronic oral NOAEL of 62-125 mg/kg bw/d in rats and a chronic LOAEL of 125 mg/kg bw/d in mice (no NOAEL established). There were no adverse systemic effects in rats and mice following sub-chronic exposure to 150 ppm PDC (NOAEL), whereas red blood cell parameters (regenerative anemia) were altered in rabbits with a LOAEL of 150 ppm in males and a NOAEL of 150 ppm in females. Body weight was slightly but statistically significantly decreased in rats only (NOAEL 15 ppm) in these sub-chronic inhalation studies, with site-of-contact (irritative) changes present in stomach (mouse, NOAEL/LOAEL 125 mg/kg bw/d after oral gavage, dependent on sex) and nasal tissue (rat, NOAEL 15 ppm after inhalation). The toxicity profile has been well-studied and documented. **No additional testing required.**

1 **Summary of repeat oral toxicity data for 1,2-dichloropropane in rats and mice (gavage administration)**

Species	Treatment	NOAEL / LOAEL (mg/kg bw/day)	Comments
Rat	0, 125, 250, 500, 1000 or 2000 mg/kg bw/d for 2 wk (n = 5/sex/dose)	NOAEL = 500	All high-dose rats died during the study, with 15% decrease in bw at 1000 mg/kg bw/day (both sexes). Reddening of the renal medullae (1000 mg/kg bw/day) was the only other toxicologically-relevant effect.
	0, 60, 125, 250, 500 or 1000 mg/kg bw/d for 13 wk (n = 10/sex/dose)	NOAEL = 250	All high dose animals and 50% of males given 500 mg/kg bw/day died early. Body weight decreased 8-16% in 500 mg/kg bw/day groups. Centrilobular congestion, hepatic fatty change and centrilobular necrosis, affecting up to 50% of high dose animals, seen microscopically.
	Males: 0, 62 or 125 mg/kg bw/day for 103 wk Females: 0, 125 or 250 mg/kg bw/day for 103 wk (n = 50/sex/dose)	NOAEL _{males} = 62 NOAEL _{females} = 125	Survival of high dose females was significantly decreased relative to low dose and control groups (males unaffected). Body weight decreased 14-24% in high dose animals (both sexes). An increased incidence of hepatic foci of clear change and liver necrosis (high dose females only) were the only lesions of note.
Mouse	0, 125, 250, 500, 1000 or 2000 mg/kg bw/d for 2 wk (n = 5/sex/dose)	NOAEL _{males} = 250 LOAEL _{females} = 125	All high-dose mice died during the study, high levels of mortality also noted at 1000 mg/kg (both sexes) and 500 mg/kg (males only). No impact on body weight of survivors. Reddening of the renal medullae common in higher dose groups (both sexes), high incidence in males given 500 mg/kg, single occurrence in all lower female dose groups.
	0, 30, 60, 125, 250 or 500 mg/kg bw/d for 13 wk (n = 10/sex/dose)	NOAEL = 500	Minor (3-5%, not clearly dose-related) reduction in body weight, no histopathological lesions present.
	0, 125 or 250 mg/kg bw/day for 103 wk (n = 50/sex/dose)	LOAEL = 125	Survival of high dose females decreased relative to control (concurrent reproductive tract infection considered cause by NTP), survival of males unremarkable. Hepatocytomegaly and hepatic focal necrosis (low and high dose males), acanthosis of the stomach (high dose males, low and high dose females) and suppurative inflammation of the reproductive tract (all females, indicative of infection) were the only histopathological changes detected.

2 **Data from NTP (1986)**

Genetic Toxicity: Gene Mutations and Chromosome Aberrations

IUCLID 5.5 and 5.6: The mutagenic potential of 1,2-dichloropropane has been evaluated in a large number of microbial tests in bacteria and fungi, both in the absence and in the presence of exogenous metabolic activation (summarized by IARC, 1999). Overall, results from these tests are mixed with both positive and negative studies and are represented in the following table.

Summary of mutagenicity findings for 1,2-dichloropropane in *Salmonella typhimurium* tester strains (from IARC, 1999).

SALMONELLA TESTER STRAIN	Result		Dose* µg/ml	Reference
	Without S9	With S9		
TA100	+	+	5000	De Lorenzo <i>et al.</i> (1977)
	-	-	565	Stolzenberg and Hine (1980)
	+	+	2900	Principe <i>et al.</i> (1981) J Sci
	(+)	-	5000	Haworth <i>et al.</i> (1983)
TA1535	+	+	5000	De Lorenzo <i>et al.</i> (1977)
	+	+	2900	Principe <i>et al.</i> (1981)
	(+)	-	5000	Haworth <i>et al.</i> (1983)
TA1537	-	-	5800	Principe <i>et al.</i> (1981)
	-	-	1666	Haworth <i>et al.</i> (1983)
	-	-	5800	Principe <i>et al.</i> (1981)
TA1538	-	-	5800	Principe <i>et al.</i> (1981)
TA98	-	-	5800	Principe <i>et al.</i> (1981)
	-	-	5000	Haworth <i>et al.</i> (1983)
TA1978	-	-	25000	De Lorenzo <i>et al.</i> (1977)

+ = positive result;

(+) = weakly positive (inconsistent response between independent repeats; <2-fold increase);

- = negative

* Either lowest effective dose (for positive study) or highest ineffective dose (for negative study)

However, in a GLP-compliant study with liquid pre-incubation conducted by the US National Toxicology Program, no mutagenic activity or cytotoxicity was detected when PDC (up to 2000 µg/plate) was incubated with four strains of *Salmonella typhimurium* (TA 98, TA 1537, TA 100, TA 1535) in the absence or presence of S9 fraction from Arochlor 1254-induced rats (NTP, 1986). A satisfactory response was obtained with the positive control substances, benzo(a)pyrene and MNNG. PDC was also not cytotoxic or mutagenic in these same tester strains when evaluated in the absence or presence of S9 using a plate incorporation methodology (up to 3150 µg/plate, in the absence or presence of glutathione supplementation; Oesch, 1979). Exposure to PDC vapor (atmosphere generated by evaporation of 0.3 - 10 ml of test

substance in a 20 l dessicator) also failed to produce a response in the organisms in the presence or absence of S9 and glutathione supplementation (Oesch, 1979), whereas dichloroethane (3 ml) was positive in TA100 and TA1535 under these same conditions.

Overall, PDC has returned consistently negative results in *Salmonella typhimurium* tester strains TA1537 and TA98 at up to 5800 µg/ml in the absence or presence of S9, whereas TA100 and TA1535 have returned inconsistent results under similar conditions.

When tested in mammalian cells *in vitro*, no mutation at the thymidine kinase locus was detected in L5178Y cells after incubation with up to 1000 nl/ml 1,2-dichloropropane in the absence of rat S9 (cytotoxic at >800 nl/ml), while assays in the presence of S9 provided evidence of mutagenicity at or around the threshold for cytotoxicity (80 nl/ml) (Myhr and Caspary, 1991). In an assessment of clastogenic potential, the number of chromosomal aberrations present in CHO cells exhibited a dose-related response (reported as a 5- or >16-fold increase) after incubation with 1370 or 1580 µg/ml PDC in the absence of S9, and an approximate 4-fold increase in the number of aberrant cells exposed to 660 or 950 µg/ml in the presence of S9 (NTP, 1986). In another series of *in vitro* experiments, CHO cells exhibited a dose-related increase in sister chromatid exchanges after exposure to PDC *in vitro*, with an approximate doubling in response after incubation with 376 or 1127 µg/ml PDC, both in the presence and absence of Arochlor 1254-induced rat S9 (NTP, 1986).

Results from a recent GLP compliant OECD 474 guideline mouse micronucleus study demonstrated no evidence of cytogenetic damage in bone marrow from CD-1 mice given up to 600 mg/kg bw by gavage (corn oil vehicle) on 2 consecutive days (Spencer *et al.*, 2003). Systemic toxicity (2° C drop in body temperature) was noted in high dose animals, while results from the range-finder investigation indicated that higher treatment levels (1000 mg/kg bw and above) were lethal. A satisfactory response was obtained with the positive control substance (cyclophosphamide). Based on toxicokinetic data demonstrating PDC is distributed evenly across all tissues, including bone, exposure of the bone marrow can be assumed for this study. The results demonstrate no potential for PDC to damage genetic material present in immature red blood cells.

Similarly, negative results were also reported from a modern, guideline rat dominant lethal assay (Hanley *et al.*, 1989) performed to GLP. Male SD rats (n = 30/group) received PDC in drinking water at doses equivalent to 0, 28, 91 or 162 mg/kg bw/day for at least 13 wk. The high dose was a saturated solution of PDC in water. They were then mated with untreated females for two successive one-week periods. A positive control group (cyclophosphamide, 100 mg/kg bw, 48 hr prior to mating) was included in the study. Mating and fertility indices were comparable between the control and PDC-treated groups (96-100%), but decreased significantly in the positive controls. Slight variations in number of corpora lutea, number of implantations, pre-implantation losses and resorptions rates were noted in the first or second week of mating in the low and high dose groups (mid-dose group not different from control), but the magnitude of the change was within the normal control ranges. In contrast, the positive control group showed a 2-fold increase in pre-implantation loss and a 10-fold increase in resorption rate. Overall it was concluded that PDC had no capacity to induce heritable mutations in male SD rats following at least 13-week oral treatment with up to 162 mg/kg bw/day.

Overall while findings from *in vitro* genotoxicity tests are inconsistent, including both positive and negative findings in bacterial and mammalian systems, results from recent GLP compliant guideline investigations demonstrate that PDC is not a somatic or germ cell genotoxicant *in vivo*, despite widespread distribution throughout the body. In addition, results from adequate carcinogenicity assays in rats and mice provide supplementary information on the mutagenic potential of 1,2-dichloropropane *in vivo*. The findings (limited to liver tumours in mice and no convincing evidence of carcinogenicity in the rat) indicate that the compound is not a genotoxic carcinogen. **No additional testing is required**

Carcinogenicity

IUCLID 5.7: The carcinogenic potential of PDC has been investigated in two long term oral gavage studies using F344 rats and B6C3F1 mice (NTP, 1986). Due to poor survival, statistical analysis of tumor incidence was adjusted for survival in both species.

No significant or treatment-related increase in tumor incidence was observed in male rats given 0, 62 or 125 mg/kg bw/day for 103 wk. Female rats given 125 or 250 mg/kg bw/day showed a positive trend for mammary adenocarcinoma incidence (adjusted rates: 3%, 5%, 27%), which was increased significantly in the high dose group. These were neither metastatic, anaplastic, nor highly invasive and were diagnosed by some NTP pathologists as highly cellular fibroadenomas (NTP, 1986). Affected high dose females showed a marked decrease in survival (32% alive at study end versus 74%-86% in the control and low dose groups) and a significant reduction (>20%) in body weight, suggesting that 250 mg/kg bw/day was in excess of the Maximum Tolerated Dose for PDC; compromised metabolic, immune, or hormonal status was possible under such conditions (NTP, 1986). It is pertinent that there was no increase in liver tumors despite the occurrence of chronic histopathological changes, including foci of clear change and necrosis. Based on these findings, NTP concluded that there was no evidence for the carcinogenicity of PDC in male rats, while in females given 250 mg/kg bw for 103 wk, there was equivocal evidence of an increased incidence of mammary adenocarcinoma; these were considered borderline malignant lesions by NTP, which occurred concurrently with decreased survival and reduced body weight gain. In mice, there was a positive trend for liver adenoma (adjusted for survival) in both sexes given 0, 125, or 250 mg/kg bw/day for 103 weeks. Tumor incidences in high dose males (45%) and both groups of treated females (17-19%) were increased significantly relative to the controls (20% in males, 3% in females). The findings in male mice occurred in the presence of hepatocytomegaly and hepatic focal necrosis in both treatment groups. The incidence of liver tumors in female mice was essentially identical in the two treated groups, despite a 2-fold difference in dose. High dose females also showed an increased incidence of thyroid tumors but this was not clearly dose-related (combined follicular cell carcinomas and adenomas, adjusted rates 3%, 0%, or 21% in control, low, and high dose groups), and occurred in the presence of liver changes (hepatocytomegaly, focal necrosis, tumors), which may have affected the metabolic and/or hormonal status of the animals. Body weights (both sexes) were unaffected by treatment, while survival at week 103 was reduced in treated females due to reproductive tract infection (70%, 58% and 52% for control, low and high dose animals; males unremarkable). NTP concluded that there was some evidence of carcinogenicity for PDC in male and female mice, based upon an increased

incidence of hepatocellular neoplasms, primarily adenomas (thyroid tumors disregarded). While the mechanism underlying these changes is unknown, the occurrence of histopathological liver lesions in male mice (LOAEL 125 mg/kg bw/day) suggests that chronic target organ toxicity may have played a contributing role in the expression of these benign tumors.

Hepatocellular adenoma is a common finding in control B6C3F1 mice. Historical control data for this lesion from contemporaneous NTP studies conducted to 1995 (corn oil, gavage, 16 studies) returned an incidence of 267/813 (33%) in males (range 14-58%) and 111/809 (14%) in females (range 2-28%) (Analytical Services Inc, 1995). Comparison of this historical control information with findings from the NTP study shows that the control incidence for males and females from this study (20%, 3%, respectively) was lower than the mean historical control data, while the incidence for high dose males (45%) and both treated females groups (17%, 19%) was below the upper bound of the historic control data. Spontaneous biological variation in the control data may therefore have influenced the results of this study. When reviewing the rat and mouse tumor findings reported by NTP, IARC (1999) concluded that 1,2-dichloropropane is not classifiable as to its carcinogenicity to humans (Group 3). Overall, these considerations indicate that PDC is not a direct-acting carcinogen, that there is equivocal evidence of an increase in mammary tumors in female rats, and that other factors (such as spontaneous biological variation) may have contributed to the increased incidence of mouse liver tumors.

No additional testing is required.

Reproductive Toxicity

IUCLID 5.8: The effect of PDC on the reproductive performance of male and female S-D rats was investigated in a GLP-compliant, guideline, 2-generation study by Kirk *et al.* (1990). PDC was administered in drinking water at levels of 0%, 0.024%, 0.1% or 0.24% (w/v), equivalent to received doses of 20-30, 70-130 or 130-250 mg/kg bw/day, respectively, for the parental generations; females received higher doses during lactation, equivalent to approx. 60, 200 and 450-500 mg/kg bw/day. Water consumption was decreased 20-50% in the mid- and high dose groups, possibly reflecting poor palatability linked to the presence of PDC. Gestational body weight gain was reduced by approximately 20% in high dose dams and 7-13% in mid dose females. Treatment-related hepatocellular granularity,

considered an adaptive change by the study pathologist, was present in males and females of both generations at all dose levels (incidence in high dose animals: $\leq 17\%$ in females; $<13\%$ for males). All other tissues, including reproductive organs from both sexes, were unremarkable. Despite the observed effects, reproductive function was unaffected in males and females of both generations. Although neonatal body weight was decreased, and neonatal mortality greater, in litters from high-dose dams consuming up to 250 mg/kg bw/d during pregnancy or up to 500 mg/kg bw/d during lactation, this appears secondary to maternal dehydration and a 20% reduction in gestational body weight gain, rather than a direct effect on reproduction. Live births, litter sizes and other pup parameters were unremarkable. Based on these findings, the study demonstrated a parental NOAEL of 20-30 mg/kg bw/day (0.024%; based upon body weight effects), a NOAEL in the offspring of 70-130 mg/kg bw/day (0.1%), and a reproductive NOAEL of 130-250 mg/kg bw/day (0.24%). Overall this study provides no evidence that PDC selectively targets the male or female reproductive system. **No additional testing is required**

Developmental Toxicity

IUCLID 5.9: The potential effects of PDC on embryonal/fetal development were investigated in two species by Kirk *et al.* (1995) in two GLP-compliant guideline studies. Pregnant S-D rats were treated with 0, 10, 30 or 125 mg/kg bw/day PDC in corn oil (gavage) on gestation days 6-15 inclusive and fetuses examined on GD 20, while pregnant New Zealand White rabbits received 0 (corn oil vehicle), 15, 50 or 150 mg/kg bw/day on GD 7-19, inclusive, followed by a fetal examination on GD 28.

Clear signs of maternal toxicity were present in high dose animals of both species. Rats given 125 mg/kg bw/day exhibited clinical signs (decreased movement and muscle tone, lacrimation, salivation) on GD 6 and 7, with an approx. 25% reduction in food and water consumption and a 30% reduction in body weight gain over the entire treatment period. Rabbits given 150 mg/kg bw/day showed a statistically significant net reduction in mean body weight gain on GD 7-20 (decreased 165 g) while controls showed a net gain (49 g) during the same period. Haematological changes were also noted in high dose rabbits (not evaluated in rats), with an approx. 20% reduction in red cell counts, haemoglobin concentration and haematocrit, while platelet and white cell counts were increased by 20-25%. Fetal examination revealed

a similarly low incidence of variations in control and treated groups of both species; the only treatment-related finding was a significant increase in delayed ossification of the bones of the skull in high dose rats and rabbits, indicative of a developmental delay. There was no evidence of any teratogenic effect. The NOAELs from this study are summarised in the following table.

Maternal and fetal NOAELs

	NOAEL (mg/kg bw/day)	
	Rat	Rabbit
Maternal toxicity	30	50
Fetal toxicity	30	50
Teratogenicity	125	150

Overall, results from these well-conducted developmental toxicity studies demonstrated the occurrence of mild fetotoxicity (delayed ossification) coincident with maternal toxicity. PDC was not teratogenic under the conditions of these investigations. **No additional testing is required**

V CONCLUSIONS

Evaluation of the existing data leads to the conclusions that a substantial quantity of data currently exist to adequately represent the toxicological and ecological screening profile of CAS 63890-96-5 C3 Chlorinated Hydrocarbon Stream, and these data support the conclusion that **no further testing is needed to satisfy endpoints for HPV/SIDS.**

1.6.3 PACKAGING

1. General Information

Id 78-87-5
Date 14.12.2004

1.7 USE PATTERN

Type of use	: use	
Category	: Intermediates	
Remark	: Used as an intermediate in the production of chlorinated solvents (perchloroethylene/tetrachloroethylene).	
Source 25.10.2004	: The 1,2-Dichloropropane ICCA/HPV Consortium	(6)
Type of use	: industrial	
Category	: Basic industry: basic chemicals	
Remark	: 1,2-dichloropropane was used as a solvent for oil, fats, caoutchouc, gum, wax and resins and also as a textile spot remover, paraffin remover, scrubbing agent ingredient, cleanser and a galvanizer. As bitumen, asphalt and tar dissolves easily in 1,2-dichloropropane it was used to manufacture construction aides and roofing. 1,2-dichloropropane is no longer used in Western Germany.	
Source 25.10.2004	: The 1,2-Dichloropropane ICCA/HPV Consortium	(7) (8) (9)
Type of use	: type	
Category	: Non dispersive use	
Remark	: 1,2-dichloropropane is and was used as a nematocide, insecticide and pesticide. Formulations of 1,2-dichloropropane and 1,3-dichloropropene are used.	
Source 25.10.2004	: The 1,2-Dichloropropane ICCA/HPV Consortium	(10) (11) (12) (8) (13) (14) (9)
Type of use	: industrial	
Category	: Agricultural industry	
Remark	: 1,2-dichloropropane was used as a nematocide, insecticide and pesticide. Commercial products such as Telone II or D-D contains 94 % 3-dichloropropene and 0,2 % 1,2-dichloropropane or 52 % 1,3-dichloropropene and 29 % 1,2-dichloropropane. At this time in the German Republic (BRD) 1,2-dichloropropane in pesticides is not allowed and is not on the market. This use type is discontinued in the U.S. and the EU. Status in other OECD countries is unclear.	
Source 25.10.2004	: The 1,2-Dichloropropane ICCA/HPV Consortium	(7) (15) (16) (17)
Type of use	: industrial	
Category	: other: flame retardants and fire preventing agents	
Remark	: 1,2-dichloropropane is used as a flame retardant during the manufacture of flame retardant rubber mixtures. It is also applied as an impregnation agent. This cited application needs further investigation as PDC is highly flammable!	
Source 25.10.2004	: The 1,2-Dichloropropane ICCA/HPV Consortium	(8) (18)
Type of use	: use	

1. General Information

Id 78-87-5
Date 14.12.2004

Category	:	Fuel additives	
Remark	:	1,2-dichloropropane is used as a lead additive in fuel additives. Given the reduction in use of leaded fuels, this use is minor.	
Source 25.10.2004	:	The 1,2-Dichloropropane ICCA/HPV Consortium	(19)
Type of use	:	use	
Category	:	Pesticides	
Remark	:	1,2 dichloropropane has been used as a nematocide, insecticide and pesticide. Formulations of 1,2-dichloropropane and 1,3-dichloropropene are applied to the above.	
Source 25.10.2004	:	The 1,2-Dichloropropane ICCA/HPV Consortium	(10) (11) (12) (8) (13) (14) (20)

1.11 ADDITIONAL REMARKS

Remark : Water Pollution

Classified by : KBwS (DE)
Labelled by : KBwS (DE)
Class of danger : 3 (strongly water polluting)
Country : Germany

Classified by : EU Commission

1. General Information

Id 78-87-5
Date 14.12.2004

Labelled by : EU Commission
Class of danger : -
Country : EU
Remark : The European Union added 1,2-dichloropropane to the "black list", which contains 129 substances of high priority chemicals. 1,2-dichloropropane is one of the 83 substances of this list with special significance for the Rhine River tributaries. At the same time these 83 substances also entered the research program of the International Rhine Commission.

Type : air
Light source :
Light spectrum : nm
Relative intensity : based on intensity of sunlight
Deg. product :
Method :
Year :
GLP :
Test substance : as prescribed by 1.1 - 1.4

Remark : 1,2-Dichloropropane does not have any chromophores that absorb wavelengths >290 nm, so direct photolysis will not be a significant fate process.

Vapour phase photolysis under simulated sunlight did not occur after prolonged exposure (period not stated).

Experimental determination of its rate of reaction with hydroxyl radicals gave a half-life of >23 days. A computer estimate of its half-life due to H-atom abstraction by hydroxyl radical yields a calculated half-life of 7.12 days. Typically measured data are more reliable than calculated data.

Remark

: I. Lifetime of 1,2-Dichloropropane

Rate of Reaction of 1,2-Dichloropropane with Hydroxyl Radical

The absolute rate constant has been measured for the gas-phase reaction of hydroxyl radicals with 1,2-dichloropropane. Experiments were carried out using the pulsed laser photolysis-laser induced fluorescence technique over the temperature range 233-372 K. The kinetic data obtained were used to derive the following Arrhenius expression:

$$k = (2.1 \pm 0.5) \times 10^{-12} \exp[-(453 \pm 76)/T] \text{ (in units of cm}^3\text{molecule}^{-1}\text{s}^{-1}\text{)}$$

The quoted errors for the pre-exponential factor, A, and E/R are given by $(\Delta A) = 2\sigma(\ln A)$ and $E/R = 2\sigma(E/R)$ respectively. At room temperature, the rate constant obtained is $(4.6 \pm 0.6) \times 10^{-13} \text{ cm}^3\text{molecule}^{-1}\text{s}^{-1}$.

The rate constant obtained at 298 K was compared with the calculated one using a quantitative structure-activity relationship (QSAR.) The calculated value, $5.2 \times 10^{-13} \text{ cm}^3\text{molecule}^{-1}\text{s}^{-1}$ was in excellent agreement with the experimental one.

Upper Limit on Rate of Reaction of 1,2-Dichloropropane with Hydroxyl Radical

The rate constant for reaction of 1,2-dichloropropane with hydroxyl radical is $< 4.4 \times 10^{-13} \text{ cm}^3 \text{ molecule}^{-1}\text{sec}^{-1}$ at 296 K (23°C) based on its rate relative to dimethyl ether. That does not contradict the work above, since the discrepancy is well within the experimental error of the measurements.

Estimation of the Lifetime of 1,2-Dichloropropane

The lifetime ($t = 1/(k[\text{OH}])$) of 1,2-dichloropropane, was estimated by using a global tropospheric 24-hour average OH radical concentration of $1 \times 10^6 \text{ molecule cm}^{-3}$ and the measured bimolecular rate constant at room temperature. The tropospheric lifetime of 25 days is relatively short and hence one should consider the oxidation products to evaluate its atmospheric impact.

II. Products of Oxidation of 1,2-Dichloropropane

The QSAR for estimating the rate of reaction of 1,2-dichloropropane with hydroxyl radicals (3) also provides an estimate of the amount of hydrogen abstraction from each carbon atom; 60% from the central carbon, 29% from the chloromethyl ($-\text{CH}_2\text{Cl}$) group and 11% from the methyl group.

The products of chlorine-initiated oxidation of a similar molecule, 1,2,3-trichloropropane have been studied. 1,2,3-Trichloropropane is oxidized through $\text{ClCH}_2\text{CCl}(\cdot)\text{CH}_2\text{Cl}$ and $\text{ClCH}_2\text{CHCl}(\cdot)\text{Cl}$ radicals which are analogous to the major radical products of H-abstraction from 1,2-dichloropropane by HO^\cdot .

The initial radicals react with oxygen to form peroxy radicals (ROO^\cdot) which are reduced, largely by reaction with NO, to alkoxy radicals (RO^\cdot).

By analogy to the decomposition of $\text{CH}_2\text{ClCCl}(\text{O}^\cdot)\text{CH}_2\text{Cl}$, which yields a majority of 1,3-dichloroacetone by Cl atom loss and some $\text{HC}(\text{=O})\text{Cl}$ and $\text{ClCH}_2\text{C}(\text{=O})\text{Cl}$ by C-C bond cleavage followed by oxidation of ClCH_2^\cdot , the

main products from 1,2-dichloropropane will be chloroacetone, acetyl chloride ($\text{CH}_3\text{C}(=\text{O})\text{Cl}$) and formyl chloride ($\text{HC}(=\text{O})\text{Cl}$) as shown in the following reactions.

The minor attack at the CH_2Cl group leads to an alkoxy radical that, by analogy to similar attack on 1,2,3-trichloropropane, will yield some CO_2 and the CH_3CHCl radical as well as uncertain amounts from other pathways leading ultimately to HCl and acetyl chloride.

Fate of Oxidation Products

Chloroacetone

Chlorination of acetone results in a red shift and increase of the UV absorption. The UV spectrum of chloroacetone much more closely resembles that of 1,3-dichloroacetone than acetone. Using the actinic flux (the quantity of light available to molecules at a particular point in the atmosphere) representative of a summer day at 40°N the photolysis lifetime for 1,3-dichloroacetone is between 30 minutes and 12 hours. The estimated photolysis half-life of acetone is ~80 days at the surface and ~30 days at 5 km at 40°N in the summer. Thus the half life of chloroacetone will be much shorter than that required for transport to the stratosphere.

The estimated lifetime of chloroacetone due to reaction with hydroxyl radicals in the atmosphere is 29 days based on $k_{\text{OH}} = 0.3682 \times 10^{-12} \text{ cm}^3 \text{ molecule}^{-1} \text{ sec}^{-1}$ and days with an average of $1 \times 10^6 \text{ molecules cm}^{-3}$ of HO^\bullet for 12 hours of daylight. Photolysis will be the main pathway of removal of chloroacetone from the atmosphere, but reaction with HO^\bullet also is sufficient to prevent significant transport of chlorine to the stratosphere.

HCl , Acetyl chloride ($\text{CH}_3\text{C}(=\text{O})\text{Cl}$) and Formyl chloride ($\text{HC}(=\text{O})\text{Cl}$)

The atmospheric fate of these compounds is expected to be incorporation into rain-cloud-fog water followed by hydrolysis and removal by wet deposition within probably 5-15 days.

Similarly, $\text{HC}(=\text{O})\text{Cl}$ and $\text{CH}_2\text{ClC}(=\text{O})\text{Cl}$, the chlorinated organic products from photooxidation of 1,2-dichloroethane, are considered to have lifetimes in the lower atmosphere which are much shorter than that required for transport to the stratosphere and so are incapable of delivering significant amounts of chlorine to the stratosphere.

III. Ozone Depletion Potential of 1,2 Dichloropropane

Based on the lifetime and the products of oxidation, emission of 1,2-dichloropropane will not put a significant amount of chlorine into the

stratosphere, and the ozone depleting potential of 1,2-dichloropropane is negligible.

IV. Global Warming Potential of 1,2 Dichloropropane

The tropospheric lifetime of 1,2-dichloropropane, based on its rate of reaction with hydroxyl radicals and the average tropospheric hydroxyl concentration, is 25 days. This is very short compared to the time horizons for global climate change.

A rough comparison to 1,1,1-trichloroethane, CH_3CCl_3 , based on a comparison of lifetimes and infrared spectra, suggests that the GWP of 1,2-dichloropropane relative to CO_2 will be 7 for a time horizon of 20 years and 2 for a time horizon of 100 years.

Thus, the global warming potential of 1,2-dichloropropane is negligible.

V. Photochemical Ozone Creation Potential (POCP) of 1,2 Dichloropropane

The potential of 1,2-dichloropropane to form ozone in polluted air, although not specifically determined, is clearly low. The POCP under the 5-day European base case is in the range of 2-25 compared to 100 for ethylene.

A rough estimate of the MIR (maximum incremental reactivity) of 1,2-dichloropropane indicates that it is within a factor of two of that of ethane, which is considered to have "negligible photochemical reactivity" by the US EPA.

Method : other (measured): Stability Test
Year : 1980
GLP : no data
Test substance : no data

Remark : In presence of activated Silica the photomineralization of 1,2-dichloropropane was examined. Activated Silica was exposed for 96 hours to a Hg-high pressure lamp (simulated sun light Lambda > 290 nm) through Pyrexglas. The determination of the photomineralization was tracked by CO₂-formation. It was observed that the oxidative degradation (build of CO₂ and Cl⁻) of 1,2-dichloropropane which is adsorbed on the surface of the Silica, highly depends on the activation of the Silica (surface catalyzed photolysis). In non-activated Silica a buildup of 1.8 % CO₂ and 3 % Cl⁻ was determined; in activated Silica buildup was 45.9 % CO₂ and 60.7 % Cl⁻. The activation highly influences the mineralization. This points to the fact that the photooxidative decrease of CO₂ takes place at the surface and not in the gaseous phase. It is yet to be known if these lab results remain the same in nature for 1,2-dichloropropane, which can adsorb to aerosol surfaces, dusts, sands etc.

Remark : The catabolism of 1,2-dichloropropane has been tested in Pyrex vessels containing demineralized water. As Pyrex absorbs wave-length < 290 nm, the sunlight spectrum of the troposphere was simulated during the irradiation. The transformation rate was 4 % after 180 minutes irradiation with 5.65 mg 1,2-dichloropropane/l starting concentration and was 8 % after 120 min irradiation with a starting concentration of 10.17 mg 1,2-dichloropropane/l. This results in the half-life times estimated at ca. 50.9 hours and 16.6 hours.

Test substance :

Remark : The half-life time was tested on an average of 2 sand grounds (organic compounds 7.7% and 1.9%; pH value 4.3 and 5.0) and 2 clay grounds (organic compounds 1.5% and 1.8%; clay content 7.9% and 17.4%; pH value 7.7 and 7.6). The grounds were enriched with 1,2-dichloropropane in closed glass vessels (9 times bimonthly). Twenty-seven months after the last addition of 1,2-dichloropropane the organic chloride content of the grounds was analyzed to determine the reduction of 1,2-dichloropropane. There was no control with contaminated or sterilized ground (only ground without the 1,2-dichloropropane enrichment).

3.2.1 MONITORING DATA

Type of measurement : background concentration

Media : ground water

Concentration : = .2 - 19.4 µg/l

Method : Limit of detection = 0.2 ug/l

Remark : Samples of untreated ground water from 1,926 rural, self-supplied domestic wells in the USA were analyzed for VOCs, including 1,2-dichloropropane, during 1986-1999. Reviewer's comment: this period covers the phase-out (1984-1989) and subsequent delisting of PDC as a soil fumigant in the USA, including a 10-yr follow-up period.

Data were compiled from two sources:

* Samples analyzed by the USGS National Water-Quality Laboratory between 1993-1999 as part of the US Geological Survey's National Water-Quality Assessment Program. Samples were analyzed using purge and trap gas chromatography-mass spectrometry.

* Samples analysed as part of an ambient ground water/source water quality monitoring program conducted by local, State and other Federal agencies between 1986-1995. Analysis was performed by a US-EPA certified laboratory (variety of methodologies, not reported).

3. Environmental Fate and Pathways

Id 78-87-5

Date 14.12.2004

Results from these analyses were included in the report only if the analytical limit of detection was 0.2 ug/l or less (i.e. 0.2 ppb or below).

PDC was present in 15/1926 samples at detected concentrations of 0.2 -19.4 ug/l, with a median of 0.5 ug/l (500 ppt).

The analyzed concentration was greater than 5 ug/l in 2 of these 15 samples, and exceeded 10 ug/l in one of those 15, essentially 1 out of 1926 total samples analyzed.

Reviewer's comment: by inference, 13/15 of the 'positive' samples contained PDC at a concentration of 0.2-5 ug/l. The vast majority of samples (1911/1926 = 99.2%) contained no detectable PDC (at a limit of detection of 0.2 ug/l or 200 ppt).

Source : The 1,2-Dichloropropane ICCA/HPV Consortium
Conclusion : 1,2-dichloropropane was present at concentrations of 0.2-19.4 ug/l in 15 of 1926 ground water sources from the USA analyzed during the period 1986-1999. Only two samples contained PDC at concentrations in excess of 5 ug/l. The vast majority of samples (1911/1926 = 99.2%) contained no detectable PDC (at a limit of detection of 0.2 ug/l).

Reliability : (2) valid with restrictions
Monitoring studies conducted by US government agency

25.10.2004

(65)

Type of measurement : background concentration
Media : air
Concentration :
Method : Limit of detection at or below 2 ppt

Remark : Measurements of urban air concentrations of 24 selected VOCs, including 1,2-dichloropropane, were conducted over periods of approx. 2 wk at 4 urban locations in the USA during the mid-1980s:

- San Jose, CA ("Silicon Valley"); April, August and December 1985 (total 35 days of sampling)
- Downey, CA; February 1984 (total 10 d)
- Houston TX; March 1984 (total 9 d)
- Denver CO; March-April 1984 (total 8 d)

Air samples were collected using a stainless steel manifold, 5 m above ground level. In the majority of locations, samples were collected 3-5 min over 1-2 hr whereas a 2 hr integrated collection regime was employed at San Jose. On average 500 ml ambient air was collected at each location, cryoconcentrated (liquid argon) and analyzed immediately by electron capture detector GC. The analytical equipment was calibrated once or twice each day using appropriate concentration standards. External audit (Northrop Services Inc., under contract to US-EPA) indicated a precision of +/-15% and accuracy of +/-30%

Reviewer's comment: no limit of detection was given for PDC however, based on results obtained, this would appear to be 2 ppt or below.

The following arithmetic mean ambient air concentrations (ppt, parts per trillion; range in parenthesis) were

Air	: 98.85 % (Fugacity Model Level I)	
Water	: .93 % (Fugacity Model Level I)	
Soil	: .21 % (Fugacity Model Level I)	
Biota	: % (Fugacity Model Level II/III)	

3. Environmental Fate and Pathways

Id 78-87-5

Date 14.12.2004

Soil : % (Fugacity Model Level II/III)
Method :
Year :

Method : Input Parameters for Level III:
Molecular Mass (g/mol): 112.99
Temperature (°C): 20
Log Kow: 2.0
Water Solubility (g/m3): 2800
Vapor Pressure (Pa): 6620
Melting Point (°C): -100.4
Fugacity ratio: 1.0

Reaction Half-lives (hr)
Air: 550
Water : 550
Soil: 1700
Sediment: 5500

Level III Emissions: 1,000 kg/hr to air only.
According to U.S. EPA TRI Database, >99.9% of reported PDC emissions are to the atmosphere.

Result : Distribution of PDC in the environment based on Level III model:

Compartment	Distribution (%)	Concentration (µg/m3)
Air	98.85	0.89
Water	0.93	4.2
Soil	0.21	10
Sediment	<0.01	6.3

Advection in air accounts for 88.6% of removal rate

Reaction in air accounts for 11.2% of removal rate

Advection and reaction in water, sediment, and soil account of 0.2% of removal rate

Source : The 1,2-Dichloropropane ICCA/HPV Consortium
Conclusion : Level I and III models predict that PDC will be predominately transported to the atmosphere, with little or no potential for deposition to soil and water. Advection is the predominant removal mechanism in the atmosphere.

Reliability : (2) valid with restrictions
Accepted computational method.

Flag : Critical study for SIDS endpoint

25.10.2004

(33) (115)

Type : adsorption
Media : water - soil
Air : % (Fugacity Model Level I)
Water : % (Fugacity Model Level I)
Soil : % (Fugacity Model Level I)
Biota : % (Fugacity Model Level II/III)
Soil : % (Fugacity Model Level II/III)
Method : other: Calculation
Year : 1980

Result : For 1,2-dichloropropane, a ground sorption coefficient Koc 299.14 can be calculated on a basis of n-Octanol/water partition coefficient log Pow 2.02 according to the formula of Kenaga and Goring (1980) $\log Koc = 1.377 + 0.544 (\log Pow)$.

3. Environmental Fate and Pathways

Id 78-87-5
Date 14.12.2004

26.10.2004 (122)

Media : water - air
Method : other (measurement)
Year :

Remark : A Henry constant at 20 degrees C for 1,2-dichloropropane was calculated at 192.52- 273.51 Pa x m³ x mol⁻¹ and at 25 degrees C, at 361.73 Pa x m³ x mol⁻¹. According to Thomas (1982) as 1,2-dichloropropane is a light volatile substance, a transition from aqueous solution of 1,2-dichloropropane evaporates in the atmosphere.
Source : The 1,2-Dichloropropane ICCA/HPV Consortium
Reliability : (4) not assignable
Not assignable; Insufficient detail in the IUCLID entry to determine reliability.

26.10.2004 (123) (45)

Media : water - air
Method : other (measurement)
Year : 1980

Remark : A water solution, enriched with 1 mg 1,2-dichloropropane/l, had a high of 1,6 cm. It was stirred at 24 degrees C with a magnetic stirrer at 100 +/- 10 U/min.

Result : In a simulation experiment 1,2-dichloropropane was de-gassed out of an aqueous solution in the laboratory and after 8 minutes it had evaporated by 50 %.

Source : The 1,2-Dichloropropane ICCA/HPV Consortium
Reliability : (4) not assignable
Not assignable; Insufficient detail in the IUCLID entry to determine reliability.

26.10.2004 (124)

Media : water - air
Method : other (measurement)
Year : 1984

Result : A relative transfer coefficient of 0.57 for 1,2-dichloropropane was determined in a laboratory experiment in a circulating current (speed 1 m x s⁻¹, 1 m depth). Based on this coefficient, the half-life time for the evaporation of 1,2-dichloropropane was approximately 6 hours.

3.4 MODE OF DEGRADATION IN ACTUAL USE

3.5 BIODEGRADATION

Type	:	aerobic
Inoculum	:	activated sludge, industrial, non-adapted
Concentration	:	150 mg/l related to Test substance related to
Contact time	:	28 day(s)
Degradation	:	(±) % after
Result	:	under test conditions no biodegradation observed
Deg. product	:	
Method	:	OECD Guide-line 302 B "Inherent biodegradability: Modified Zahn-Wellens Test"
Year	:	2002
GLP	:	yes
Test substance	:	as prescribed by 1.1 - 1.4
Method	:	Reaction mixtures were prepared by adding 150 mg/L PDC directly to activated sludge (1,000 mg/L mixed liquor suspended solids) in a defined mineral medium. The test vessels were sealed to minimize the loss of PDC due to volatilization. Oxygen concentrations in the headspace of the vessels were monitored and oxygen gas was added as necessary to ensure that aerobic conditions were maintained.

	<p>Abiotic control mixtures were prepared by adding PDC to activated sludge inhibited with mercuric chloride. Positive control mixtures were prepared with aniline added to activated sludge to confirm the viability of the microbial inoculum. Toxicity controls were prepared with aniline and PDC in activated sludge to determine if the test compound was inhibitory to the microbial inoculum. The reaction mixtures were continuously mixed and incubated at 22 ± 1 °C for 28 days.</p> <p>Reaction mixtures were sampled after 0, 1, 2, 7, 14, 21, and 28 days to measure PDC and dissolved organic carbon (DOC) concentrations remaining in the mixtures. PDC concentrations in the reaction mixtures were determined by gas chromatography with flame ionization detection (GC-FID). Removal of aniline was determined by dissolved organic carbon (DOC) analyses of the reaction mixtures.</p> <p>PDC and DOC concentrations were reported as the arithmetic mean of analyses from duplicate reaction mixtures.</p>
Result	<p>: No biodegradation of PDC was observed in the test. No difference was observed in loss of PDC in viable mixtures compared to abiotic controls over 28 days.</p> <p>Aniline (reference compound) was extensively degraded in positive control mixtures (96% in 14 days), thereby confirming the viability of the microbial inoculum.</p> <p>Extensive degradation of aniline in toxicity control mixtures containing PDC (98% in 14 days) showed that PDC was not inhibitory to the inoculum under the test conditions.</p>
Source	: The 1,2-Dichloropropane ICCA/HPV Consortium
Conclusion	: PDC did not meet the criteria of inherent biodegradability under the conditions of a modified OECD Method 302B test.
Reliability	: (1) valid without restriction GLP guideline study.

Inoculum : other: effluent from a university sewage treatment plant
Concentration : 70 mg/l related to Test substance related to
Deg. product :
Method : other: Filtration Test
Year : 1981
GLP : no data
Test substance : no data

Remark : The decrease of 1,2-dichloropropane was tested on a pilot machine using the meadow filtration method. Grass was planted on the filtration area (ground temperature was 20 - 22 degrees C). For 2 months before testing, they brought in the effluent sewage from a university. The established 1,2-dichloropropane elimination was 74 %. The question remains if 1,2-dichloropropane was eliminated through evaporation or from a biological decrease. In a "Leaching test" only "non-spiked" waste water was used. One day after the "Leaching test" began 1,2-dichloropropane was no longer found in the water samples along the filtration installation. We can conclude that a reversal adsorption did not take place.

Laboratory-reared Fathead minnows were used in these studies. The fish were 30 - 35 days old at the time of the test.

Test conditions

Testing was carried out at 25 degrees C in all-glass aquaria with a working volume 41 l. Water from Lake Superior was used as the exposure medium. Fifty fish were randomly assigned to 12 exposure tanks, comprising five test concentrations plus a control, in duplicate. A 'saturator system' was used to prepare a stock solution of PDC, and the lower exposure concentrations prepared at a dilution spacing of 0.6 (however the actual exposure concentrations used are not stated in the paper). Fish were not fed during the period of the test. Water flow through the tanks was greater than 10 tank volumes per day. Dissolved oxygen, hardness and alkalinity were determined at least once daily on a control, intermediate and high exposure tank. Fluorescent lighting and a 16 hr photoperiod was used (48 lumens at the water surface).

Analysis

GC with ⁶³Ni electron capture detection was used to quantify

	the concentration of PDC in the test solutions.	
	Determination of LC50 The LC50 concentration was determined using the Trimmer Spearman-Kärber method for estimating median lethal concentrations (Hamilton, MA et al. (1977) Environ Sci Technol, 11, 714; ibid (1978) 12, 417).	
	Statistics No further statistical methods were applied to these data.	
Result	: The pH of the test solutions was 6.7 - 7.6, dissolved oxygen 7.6 - 9.2, hardness 45.0 - 45.5 mg/l CaCO ₃ , alkalinity 35.6 - 43.3 mg/l CaCO ₃ .	
	Recovery of PDC from the exposure solutions was 99 +/- 4%.	
	General signs of toxicity included lethargy and anaesthesia.	
	LC50 values (with 95% CI) were as follows:	
	24 hr = 194 mg/l (184 - 205)	
	48 hr = 154 mg/l (144 - 166)	
	72 hr = 141 mg/l (132 - 151)	
	96 hr = 140 mg/l (131 - 150)	
Source	: The 1,2-Dichloropropane ICCA/HPV Consortium	
Conclusion	: The LC50 of PDC in Fathead minnow (<i>Pimephales promelas</i>) under flow through conditions was 140 mg/l (CI = 131 - 150).	
Reliability	: (2) valid with restrictions Test procedure in accordance with national standard methods and described in sufficient detail.

4.2 ACUTE TOXICITY TO AQUATIC INVERTEBRATES

Type	:	flow through
Species	:	Daphnia magna (Crustacea)
Exposure period	:	48 hour(s)
Unit	:	mg/l
NOEC	:	= 8.3
EC50	:	= 55.9
Analytical monitoring	:	yes
Method	:	other: EPA OTS 797.1330
Year	:	1988
GLP	:	yes
Test substance	:	as prescribed by 1.1 - 1.4
Method	:	The acute LC50 of PDC in Daphnia magna was determined as part of an invertebrate chronic toxicity study.
		Test organism and conditions Daphnia magna brood stocks were acclimated under static

conditions (period not stated) and fed Selenastrum capricorneutum daily throughout the test. Culture medium was carbon-filtered dechlorinated tapwater (hardness 160-180 mg/l CaCO₃; pH 8.1-8.3; conductivity 480-624 umho/cm; 8.5-9.4 mg/l oxygen). All glassware was solvent/acid washed prior to use. The test method was based upon EPA OTS 797.1330.

Ten daphnids per treatment level were housed inside a glass exposure chamber, which was placed in a 600 ml glass beakers containing 500 ml of medium. The beakers were loosely covered to reduce volatilisation of PDC from the test solution. The test was conducted at 20 +/- 2 degrees C with a 16 hr light / 8 hr dark cycle but no aeration. Dissolved oxygen, conductivity, pH and temperature in each vessel were recorded at 24 hr intervals during the test.

The calculated nominal concentration of PDC in the test vessels was 0, 7.5, 12.0, 21.0, 36.0 and 60.0 mg/l. The medium inside the test vessels was replaced with fresh medium on average 42 times per day. Samples of test medium were removed from the replicate vessels on days 0, 7, 14 and 21 and analysed using GC (limit of detection 0.02 mg/l).

The number of live daphnids and occurrence of sub-lethal effects (immobilisation, abnormal behaviour, abnormal appearance) were recorded daily.

Statistical analysis

The data were analysed using ANOVA and Dunnett's test, and Probit, moving average and binomial techniques used to calculate the 24 hr and 48 hr LC50.

Result

: Mean, measured concentrations of PDC in the test vessels were 0, 8.3, 15.8, 21.5, 39.5 and 72.9 mg/l.

Physico-chemical parameters recorded daily throughout the 21 days of this flow-through study were as follows:

Oxygen: 8.5-9.4 mg/l

pH: 8.1-8.3

Conductivity: 480-624 umho/cm

Temperature: 20.0-21.5 degrees C

Daphnids exposed to 72.9 mg/l DCP were unable to maintain their position in the water column immediately after being placed in the test vessels, while those exposed to 39.5 mg/l were immobilised from day 2. Sub-lethal effects (smaller size, lighter colour) were noted in daphnids exposed to 21.5 mg/l.

There was no mortality at 24 hr or 48 hr in vessels containing 8.3 - 39.5 mg/l PDC. 10-20% mortality was recorded at 24 hr, and 90 - 100% at 48 hr, after exposure to 72.9 mg/l.

The calculated 24 hr and 48 hr LC50 values for lethality in *Daphnia magna* under flow-through conditions were >72.9 mg/l and 55.9 mg/l, respectively.

Source

: The 1,2-Dichloropropane ICCA/HPV Consortium

Conclusion

: Under the flow-through conditions used in this test, the 48 hr LC50 of PDC in *Daphnia magna* was 55.9 mg/l.

Reliability

: (2) valid with restrictions
GLP guideline study.

4.3 TOXICITY TO AQUATIC PLANTS E.G. ALGAE

Species	:	Skeletonema costatum (Algae)
Endpoint	:	biomass
Exposure period	:	120 hour(s)
Unit	:	mg/l
NOEC	:	= 7.4 - 18 measured/nominal
Limit test	:	
Analytical monitoring	:	yes
Method	:	EPA OTS 797.1050
Year	:	1988
GLP	:	yes
Test substance	:	as prescribed by 1.1 - 1.4

Method

: Test organism and conditions
Skeletonema costatum in logarithmic growth phase and grown on synthetic marine algal assay nutrient medium was used as the inoculum for the test. All glassware was thoroughly cleaned with non-phosphate detergent, then rinsed with hydrochloric acid, deionised water and medium prior to use. Assays (volume 25 ml) were conducted in 125 ml Erlenmeyer flasks fitted with Teflon-lined screw-capped lids. One set of replicate flasks was prepared for each study day, and discarded after sampling.

Range finding test

A range finding test was conducted to determine concentrations to be used in the definitive study. Assays were conducted in duplicate, with nominal concentrations of 1, 10, 100 and 1000 mg/l. Exposure was for 5 days. Analysis of PDC content was performed on study days 0, 3 and 5.

Definitive test

Five test concentrations (10, 18, 32, 56 and 100 mg/l) and a control were prepared in triplicate. Analysis of the PDC content of the flasks (GC -FID) was carried out on study days 0, 2, 3, 4 and 5. Algal biomass (Coulter counter, 3 counts per replicate) was determined on days 2, 3, 4 and 5 of the exposure phase, and again during a recovery phase (see below). A parallel set of control flasks with foam stoppers was also prepared to monitor algal growth under conditions open to the atmosphere.

Microscopic counts of individual cells (improved Neubauer hemacytometer) were also made on one flask each of the highest test concentration, an intermediate test concentration and a control on day 5 of the study.

The cultures were incubated at 20 (+/-2) degrees C with illumination of 4306 (+/-646) lux with a photoperiod of 14 hr light:10 hr dark. Flasks were shaken manually on each sampling day.

Determination of algistatic and algicidal effects

Aliquots from the 56 mg/ml and 100 mg/ml vessels (where culture counts were similar to or lower than the initial inoculum level) were either subcultured into fresh medium and cell growth determined on days 2, 6 and 9 (recovery experiment), or stained with Evans Blue stain and examined microscopically (living cells exclude stain).

AUC calculation to estimate PDC content of test medium

Due to the highly variable results obtained from the analytical determinations, the measured water dissipation rates for PDC in algal medium were determined by Woodburn and used to calculate the overall residual amounts of test substance present in the flasks. This was expressed as the time weighted average (TWA) concentration, and was based upon the area under the concentration curve. It follows methods developed in Annex 6 of the updated OECD Guideline 202, part II (Daphnid reproduction test, revised January 1996). The integrated area is considered by OECD to be the best expression of the dose to which aquatic organisms are exposed over the selected time period. Further information is given in Attachment 4.3AUC.

	<p>Statistical analysis</p> <p>Analysis of variance and two multiple range tests (Tukey's test, Scheffe's test) were applied to the cell count data.</p>
Remark	<p>: Although closed vessels were used, significant loss of PDC from the test vessels was evident. While a general trend of decreasing algal growth with increasing nominal exposure concentration was apparent, the analysed concentrations for each nominal value were sufficiently variable to preclude determination of an EC50 value from the data. The data were, however, adequate for derivation of a NOEC value. The reliability of this determination has been enhanced through additional 'area under the curve' calculations performed subsequently by scientists from the laboratory performing the study.</p>
Result	<p>: Analytical results</p> <p>Mean analysed concentrations on day 1 were in a range 57-75% of nominal. From day 2 onwards, however, there was little consistency either between results obtained within a set of replicate flasks or between the analysed and nominal concentrations. It was concluded that significant losses had occurred despite use of screw-capped vessels.</p> <p>Calculated TWA concentrations</p> <p>The calculated TWA concentrations for PDC on exposure days 3, 4 and 5 are shown in Attachment 4.3a. The application of first-order kinetics to the dissipation of PDC in algal media is presented in Attachment 4.3b.</p> <p>Cell counts</p> <p>Mean values for the three replicate flasks were highly variable, reflecting the analytical results. This information is summarised in Attachment 4.3c. No clear concentration-response relationship is evident, as would be expected given the analytical results, although there was a trend of reduced algal growth in the two highest nominal test concentrations.</p> <p>Comparison of mean cell counts from the screw-capped- and foam stoppered controls revealed a 65-73% reduction in growth in the capped vessels.</p> <p>Microscopic counts were lower than counts obtained using the Coulter counter, however this did not appear to have any significant impact on the overall interpretation of the data.</p> <p>Little growth occurred in algal populations from the two highest test concentrations during the recovery period. Growth in the control samples was also poor, suggesting that insufficient cells had been used to inoculate the recovery vessels. No conclusion could therefore be reached concerning possible algistatic and algicidal effects of PDC.</p> <p>Microscopic examination of Evans blue stained cells from the 56 mg/l and 100 mg/l vessels was inconclusive since it was difficult to discriminate between stained and unstained cells. Approx. 8% of cells from the 56 mg/l culture, and 20% of cells from the 100 mg/l culture, appeared dead.</p> <p>Determination of IC50 value</p> <p>No scientifically valid estimate of the IC50 for PDC was possible given the highly variable results obtained for</p>

	algal growth and analysed concentration.	
	No Observed Effect Concentration ANOVA and multiple range tests indicated that there were no significant differences between mean cell counts in the 10 mg/l and 18 mg/l nominal concentrations and the controls on any of the exposure days. In contrast, mean cell counts obtained from the other concentrations did differ significantly from controls. The authors conclude that the 5 day NOEC for PDC in <i>Skeletonema costatum</i> is 18 mg/l (nominal).	
Source	: The 1,2-Dichloropropane ICCA/HPV Consortium	
Attached document	: Attachment 4.3 AUC.doc Attachment 4.3a.doc Attachment 4.3b.doc Attachment 4.3c.doc	
Conclusion	: Under the conditions of the test, the 5-day NOEC for PDC in <i>Skeletonema costatum</i> was 18 mg/l based on nominal values, and 7.4 mg/l using analysed concentrations and a TWA technique to integrate the dose to which the algae were exposed.

4.5.1 CHRONIC TOXICITY TO FISH

Species : Pimephales promelas (Fish, fresh water)
Endpoint : other: survival, growth
Exposure period : 28 day(s)
Unit : mg/l
NOEC : = 6 - 11
Analytical monitoring : yes
Method :
Year : 1982
GLP : no data
Test substance : as prescribed by 1.1 - 1.4

Method : General
 Prior to starting the Early Life Stage (ELS) test, the 96 hr LC50 was determined using 30 day old fish. This was followed by 6-10 day range-finding test using 24 hr old larvae. The objective of both tests was to identify the lowest concentration that caused abnormal behaviour (erratic swimming, lethargy, decreased feeding etc) in the test organisms. This concentration was used as the highest concentration for the ELS study.

Test organisms and housing

All organisms were reared in the laboratory performing the study. Exposure of eggs and larvae took place in glass tanks (nominal volume 500 ml, water depth 4.5 cm) under continuous flow conditions (90% of the test solution replaced every 75 min).

For the main ELS test, 30 eggs (2-8 hr old) were placed in 4 replicate tanks per exposure concentration and observed until hatching (ie 4-5 days post-spawn). Fifteen healthy larvae per tank were then selected at random, placed in each of 4 replicate chambers and survival followed for 28 days. Body weight was determined at the end of the test. The fish were fed shrimp nauplii throughout the study.

Test conditions

Filtered, UV-sterilised water was obtained from Lake Superior, and had the following characteristics: hardness 45 mg CaCO₃/l; alkalinity 42 mg CaCO₃/l; pH 7.4; dissolved oxygen 7 mg/l. Illumination was provided by cool white fluorescent lamps with a 16 hr light period. Water temperature was 25 degrees C. Exposure concentrations of 0, 6, 11, 25, 51 and 110 mg/l (obtained by diluting a stock saturated solution of PDC in water) were used.

Analytical

The concentration of PDC in the tanks was measured twice per week in alternate replicate tanks using GC (limit of detection 0.1 mg/l).

Statistics

Hatchability of embryos, normal larvae at hatch and survival and mean weight and length data were subject to ANOVA with an F test and Dunnett's test.

Remark : Inspection of the results from this study provides the following NOEC values (LOEC in brackets):

Hatchability: 110 mg/l (>110 mg/l)

Result	<p>Normal larvae at hatch: 25 mg/l (51 mg/l) Survival to day 28: 11 mg/l (25 mg/l) Weight at day 28: 6 mg/l (11 mg/l) : Measured exposure concentrations were 0, 6, 11, 25, 51 and 110 mg/l.</p> <p>Embryo hatchability was 96% - 98%, with no treatment-related differences apparent, however the percentage of normal larvae was decreased significantly in the 51 mg/l and 110 mg/l tanks (decreased 33% and 100%, respectively).</p> <p>Body weight at day 28 was reduced significantly in larvae exposed to 11 mg/l and above, while larval survival was significantly decreased at 25 mg/l and above.</p> <p>The authors estimate that the Maximum Acceptable Toxicant Concentration (MATC, defined as a hypothetical toxic threshold falling mid-way between the NOEC and LOEC) for PDC is 59 mg/l.</p>
Source	: The 1,2-Dichloropropane ICCA/HPV Consortium
Conclusion	: Under the conditions of this ELS test in Fathead minnows, a chronic NOEC of 6 mg/l was obtained for growth and a chronic NOEC of 11 mg/l obtained for survival.
Reliability	: (2) valid with restrictions Test procedure in accordance with generally accepted scientific methods and described in sufficient detail.
Flag	: Critical study for SIDS endpoint
25.10.2004	(139)
Species	: Pimephales promelas (Fish, fresh water)
Endpoint	: other: weight of young fish
Exposure period	: 28 day(s)
Unit	: mg/l
MATC	: = 5 - 12
Analytical monitoring	: yes
Method	: OECD Guide-line draft "Early Life Stage Test (ELS-Test)"
Year	: 1976
GLP	: no data
Test substance	: no data
Remark	: The test was made with eggs 2 - 5 days old. An exposition to 25 mg 1,2-dichloropropane/l significantly ($p = 0.05$) delayed the survival rate of the fish after 28 days. A concentration of 51 mg/l, measured in flow-through, caused a significantly ($p = 0.05$) higher deformity rate in the hatched larva. The MATC-value gives the hypothetical toxic threshold concentration, which is located as the geometrical average between the concentration that causes no effect (NOEC). The next level tested caused a significant toxic effect (LOEC).

4.5.2 CHRONIC TOXICITY TO AQUATIC INVERTEBRATES

Species	: Daphnia magna (Crustacea)
Endpoint	: reproduction rate
Exposure period	: 21 day(s)

Unit	: mg/l
NOEC	: = 8.3 measured/nominal
LOEC	: = 15.8 measured/nominal
Analytical monitoring	: yes
Method	: EPA OTS 797.1330
Year	:
GLP	: yes
Test substance	: as prescribed by 1.1 - 1.4
Method	<p>: Test organism and conditions</p> <p>Daphnia magna brood stocks were acclimated under static conditions (period not stated) and fed Selenastrum capricorneutum daily throughout the test. Culture medium was carbon-filtered dechlorinated tapwater (hardness 160-180 mg/l CaCO₃). All glassware was solvent/acid washed prior to use. The test method was based upon EPA OTS 797.1330.</p> <p>Ten daphnids per treatment level were housed inside a glass exposure chamber, which was placed in a 600 ml glass beakers containing 500 ml of medium. The beakers were loosely covered to reduce volatilisation of PDC from the test solution. The test was conducted at 20 +/- 2 degrees C with a 16 hr light / 8 hr dark cycle but no aeration. Dissolved oxygen, conductivity, pH and temperature in each vessel were recorded at 24 hr intervals during the test.</p> <p>The calculated nominal concentration of PDC in the test vessels was 0, 7.5, 12.0, 21.0, 36.0 and 60.0 mg/l. The medium inside the test vessels was replaced with fresh medium on average 42 times per day. Samples of test medium were removed from the replicate vessels on days 0, 7, 14 and 21 and analysed using GC (limit of detection 0.02 mg/l).</p> <p>The number of live daphnids and occurrence of sub-lethal effects (immobilisation, abnormal behaviour, abnormal appearance) were recorded daily.</p> <p>Statistical analysis</p> <p>The data were analysed using ANOVA and Dunnett's test, and Probit, moving average and binomial techniques used to calculate the 24 hr and 48 hr LC50. The 21-day NOEC and LOEC were calculated by observing which concentration produced responses.</p>
Result	<p>: Mean, measured concentrations of PDC in the test vessels were 0, 8.3, 15.8, 21.5, 39.5 and 72.9 mg/l.</p> <p>Daphnids exposed to 72.9 mg PDC/l were unable to maintain their position in the water column immediately after being placed in the test vessels, while those exposed to 39.5 mg/l were immobilised from day 2. Sub-lethal effects (smaller size, lighter colour) were noted in daphnids exposed to 21.5 mg/l.</p> <p>The 21 day NOEC for reproduction was 8.3 mg/l and the LOEC 15.8 mg/l.</p> <p>The 21 day NOECs and LOECs for sub-lethal effects (immobilisation, size, colour) and death were 15.8 mg/l and the LOEC 21.5 mg/l, respectively.</p>
Source	: The 1,2-Dichloropropane ICCA/HPV Consortium
Conclusion	: Under the flow-through conditions used in this test, the 48 hr LC50 of PDC in Daphnia magna was 55.9 mg/l, while the 21

	day NOEC and LOEC for reproduction were 8.3 mg/l and 15.8 mg/l, respectively.

Method	<p>: Test organism and conditions</p> <p>Mysid cultures (<24 hr old) were maintained in natural sea water (salinity: 20 parts per thousand) at 25 degrees C for 10 days prior to starting the test.</p> <p>Exposure of the test organisms took place in glass aquaria (vol approx 6.8 l). Fresh medium, containing PDC, was pumped into each aquarium and provided approx. 11.8 volume additions per day. The mysids were fed brine shrimp nauplii during the test.</p> <p>The final nominal concentration of PDC in the vessels was 0, 0.6, 1.2, 2.3, 4.6 and 9.3 mg/l (each in duplicate). Water samples were collected from the chambers on study days 0, 7, 14, 21 and 28 and their PDC content analysed using GC-electron capture.</p> <p>At the start of the test, 40 post-larval mysids per treatment were selected at random and evenly distributed between four chambers housed within two replicate vessels per treatment. On test day 16, each female within a treatment replicate was paired with a male from the same treatment group, the pairs isolated within their treatment groups until study termination. The number of dead mysids, the time to release of broods, length of adults on day 15 and the number of off-spring produced were recorded. (All off-spring were maintained in the same test concentration as the parents until the end of the test.)</p> <p>Salinity, temperature and dissolved oxygen were measured regularly during the test.</p> <p>Statistical analysis</p> <p>The data were analysed using ANOVA and Dunnett's test after verifying homogeneity of the variances using Bartlett's test.</p>	
Remark	: The NOEC for parental and larval mortality, number of off-spring per female and time to release of first brood, and adult growth was 4.09 mg/l.	
Result	<p>: Analysed exposure concentrations</p> <p>Mean analysed concentrations of PDC in the test vessels were 0.41, 0.97, 1.35, 2.48 and 4.09 mg/l, however mechanical problems with the diluter apparatus meant that individual analysed values on days 0-28 were variable (i.e. in a range</p>	

0.36-0.61, 0.51-1.83, 1.24-1.57, 1.89-3.20 and 2.96-4.99 mg/l for the 0.6, 1.2, 2.3, 4.6 and 9.3 mg/l exposure groups, respectively).

Mortality

Parental mortality varied from 22% in cultures exposed to 0.97 or 1.35 mg PDC/l to 28% in cultures exposed to 0.41 or 4.09 mg/l. Mortality in controls was 10%. There was no statistically significant difference between mortality in the control or treated groups. Overall survival of juveniles from

treated parents varied from 85% in the 4.09 mg/l group to 91% in the 0.41 mg/l group, with 85% survival in the controls.

Number of off-spring and time to first brood release

The average number of off-spring per female varied from 6.8 in the 4.09 mg/l group to 10.6 in the 2.48 mg/l group, with 11.3 young/female in the controls (not significant). Mean time to first brood release was 15.5 or 16.0 days in the treated mysids versus 16.5 days in the controls. These differences were not statistically significant.

Adult growth

Mean length of adults after 15 days and 28 days exposure, and adult weight at termination, were unaffected by treatment.

Source : The 1,2-Dichloropropane ICCA/HPV Consortium
Conclusion : Under the conditions of the test, the 28 day NOEC for mortality, reproduction and growth in the mysid shrimp over 28 days was at least 4.09 mg/l, the highest concentration tested.

Species : *Mysidopsis bahia* (Crustacea)

Endpoint : mortality

Exposure period : 28 day(s)

Unit : mg/l

NOEC : = 4.09

Analytical monitoring : yes

Method : other: Chronic Toxicity Test

Year : 1988

GLP : no data

Test substance : other TS: purity = 99.9 %

Remark : The test was made in lightly covered vessels, using through-flow system, with naturally filtered seawater. The chronic toxicity was tested on animals < 24 hours old. The animals were exposed to 5 different concentrations of 1,2-dichloropropane (nominal: 0.6, 1.2, 2.3, 4.6 and 9.3 mg/l). No significant effects were observed on the parameters' parents and F1 mortality, longitudinal growth of the parents and on reproduction for the highest tested actual concentration of 4.09 mg/l (^= NOEC). The actual concentration varied as the dilution and mixboxes were modified three times. In rating the tests one must consider that the average measured concentrations (related to the dilution level) were

	between 0.41 - 4.09 mg/l - this means 81 % - 44 % of the nominal concentration.

Chambers, atmosphere and analysis
The chamber was constructed of Teflon-lined plastic, and allowed the simultaneous exposure of 8 rats (4 male, 4 female; housed on two tiers) during exposure. It was designed to permit collection of blood samples during exposure. Vapors were generated by pumping the contents of SARAN bags filled with measured volumes of 14C-PDC and dry compressed air into the chambers. The concentration of PDC at one point in the upper and the lower tier was determined by GC/FID, with LSC to quantify the concentration of radio-label.

Other details
All other methods etc were as decribed in the preceeding record.

96 / 96

PDC for males/females in the low, mid and high exposure groups, respectively.

The distribution of recovered radioactivity is summarized in Attachment 5.0b. In summary, urine (54-66% of recovered dose) and expired air (15-23% as carbon dioxide) were the principle routes of excretion with smaller amounts present in tissues and carcass (6-10%) and faeces (6-10%). Less than 4% of the recovered radioactivity was present in cage washings. Exhaled volatiles accounted for 2-3% of the dose in animals exposed to 5 ppm and 50 ppm, and 6-7% in the 100 ppm group (high dose group significantly different from mid and low dose groups). The pattern of excretion did not differ between males and females.

Analysis of tissues

Radioactivity was distributed among all the tissues examined and generally represented less than 0.18% of the recovered dose/g wet weight. The liver and kidneys contained the highest amount of radioactivity, accounting for 0.1-0.3% and 0.1-0.2% of the dose/g wet weight, respectively. There were no obvious differences in tissue distribution between the sexes or in distribution or concentration for the different exposure concentrations.

Timecourse for elimination

Urinary elimination of radiolabel was greatest over the first 24 hr post-dosing (47-62% of dose) relative to the following 24 hr (2-9%). Comparative figures for exhaled carbon dioxide were 13-20% and <3%, and 5-8% and 0.7-3.0% for faeces (at 0-24 and 24-48 hr, respectively). The majority of exhaled volatiles were also eliminated during the 24 hr following exposure, with <0.03% detected during the 24-48 hr time period.

Blood concentrations in both sexes were generally at a maximum 4 hr into the exposure (exception: 5 ppm females which peaked at 1 hr). In both sexes the peak blood PDC level was not proportional to dose indicating a dose-dependent non-linearity in clearance. The concentration in blood was below the limit of detection (0.03 ug/g) 2 hr after exposure ended. Modelling (one-compartment open model with linear fit) indicated a post-exposure blood clearance half life for PDC of 30 min in males and 24 min in females.

In plasma, the highest concentration of ¹⁴C in both sexes was found at 4 hr in the exposure, and ranged from 2, 12-15 and 27-29 ug eq/g plasma present in the 5, 50 and 100 ppm groups respectively. Corresponding AUCs were 21-23, 130-134 and 288-320 ug g⁻¹, respectively. Comparison of the 5 ppm peak plasma ¹⁴C level and AUC with the mid- and high dose groups indicated that plasma ¹⁴C was less than proportional to dose.

Metabolites

Approx. 60-90% of the radioactivity present in the exhaled volatile fraction was unchanged PDC. HPLC analysis of urine (pooled from the 3 inhalation experiments) revealed the presence of three n-acetylcysteine conjugates of PDC

(N-acetyl-S-(2-hydroxypropyl)-L-cysteine, N-acetyl-S-(2-oxopropyl)-L-cysteine and N-acetyl-S-(2-carboxyethyl)-L-cysteine) but no detectable parent compound. Attempts to identify four other HPLC peaks were unsuccessful.

Source : The 1,2-Dichloropropane ICCA/HPV Consortium

Attached document : Attachment 5.0b.doc

Conclusion : Urine and exhaled carbon dioxide were the principle routes for elimination of PDC in male and female rats after 6 hr inhalation exposure to 5, 50 or 100 ppm. The majority of radioactivity was excreted within 24 hr, with little unchanged PDC present.

Reliability : (1) valid without restriction

Method : Animals and treatments

Male and female F344 rats (7 wk old; n=4/sex) were given a single oral treatment of 1 or 100 mg/kg bwt 14C-labelled PDC (50 or 500 uCi/kg bwt, respectively) in corn oil. A third group received 7 daily oral doses of 1 mg/kg bwt non-radiolabeled PDC, followed by a single oral dose of 1 mg/kg bwt 14C-labeled PDC on day 8. Food was withdrawn 16 hr prior to dosing, and returned 4 hr post-treatment. The animals were housed in glass metabolism cages, and urine, feces and expired carbon dioxide and volatile substances collected for up to 48 hr post-dosing. The concentration of 14C in plasma (indwelling jugular cannula) was determined repeatedly during post-dosing period. Samples of body tissues (blood, bone, brain, liver, kidneys, fat, gonads, lung, heart, skeletal muscle, spleen, skin and carcass) were analysed for radioactivity at 48 hr.

Test samples

The unlabelled material was 99.9% pure. The labelled material was 97% pure, had a specific activity of 17

mCi/mmol and was uniformly labelled on a single carbon atom.

Analytical methods

Total radioactivity in urine (plus distilled water cage rinse) and blood (plasma) was quantified by liquid scintillation counting (LSC). Feces were processed using a sample oxidiser, the released carbon dioxide trapped in 1-methoxy-2-propanol:monoethanolamine (7:3) and radioactivity determined by LSC; exhaled carbon dioxide was quantified in an analogous manner. Exhaled volatile compounds were trapped on activated charcoal, desorbed (hexane) and subject to LSC.

Major urinary metabolites were separated by reverse phase HPLC both before and after acid hydrolysis. Metabolite identification was by full-scan chemical ionization-GC/MS.

Kinetic analysis

The data were fitted to a one compartment open pharmacokinetic model with zero-order input rate, and half-lives calculated, using the SIMUSOLV computer programme (Mitchell and Gauthier Associates, Inc, Concord, MA).

Statistical analysis

ANOVA and Tukeys test were applied to the data.

Result

: Recovery of radioactivity

Results for the recovery and excretion of radioactivity following oral administration of PDC are given in Attachment 5.0a.

Single dose:

In summary, urine (46-52%) and expired CO₂ (23-36%) accounted for over two-thirds of the dose, with smaller amounts present in tissues and carcass (7-11%) and faeces (7-8%). Less than 3% of the dose was present in cage washings. Exhaled volatiles accounted for 0.3-1.1% of the dose in animals given 1 mg/kg bwt, and 10-16% of the administered radioactivity in high dose animals. Overall, 100-107% of the radiolabel was recovered.

The proportion of the dose excreted as CO₂ was significantly lower in rats given 100 mg PDC/kg bwt relative to that for rats given 1 mg/kg; conversely exhalation of radioactivity in the volatile fraction was significantly greater than in the low dose group. While the pattern of excretion was generally similar in males and females, statistical analysis indicated less of the dose was excreted as CO₂ and more in the urine in females compared to males.

Multiple doses:

While the overall pattern of excretion and recovery of ¹⁴C-label was comparable to that seen in animals given a single treatment, there was a statistically significant decrease (approx. 10%) in percentage recovered in urine from the repeat dose animals. Elimination of ¹⁴C-CO₂ was slightly but significantly increased in the repeat dose group for females.

Analysis of tissues

Radioactivity was distributed among all the tissues examined. The liver contained the highest amount (0.2-0.4% of the dose /g wet weight), with generally 0.1% or less

present in the other organs. There were no obvious differences in tissue distribution between the sexes or the different dosing regimens.

Timecourse for elimination

Elimination was greatest over the first 24 hr post-dosing, with negligible amounts eliminated during the 24-48 hr period. In urine, 35-50% of the dose was recovered during the first 24 hr, with trace amounts (1-2%) excreted subsequently. Comparative figures for exhaled carbon dioxide were 21-33% and 2-3%, and 5-7% and 0.5-1.0% for faeces (at 0-24 and 24-48 hr, respectively).

In plasma, the highest concentration of ¹⁴C in both sexes was found at 4 hr post-dosing, with 0.3-0.4 ug eq/g plasma present in low dose animals and 24-28 ug eq/g plasma in animals given 100 mg/kg bwt. Corresponding AUCs were 4.2-5.4 ug g⁻¹ and 351-368 ug g⁻¹, respectively. These results suggest that levels in plasma were slightly less than dose-proportionate (perhaps indicating saturation of biotransformation at the higher dose).

There were no obvious differences in timecourse for elimination between the sexes or the different dosing regimens used in the study.

Metabolites

Approx. 82% of the radioactivity present in the exhaled volatile fraction was unchanged PDC. No unchanged PDC was present in urine. Three n-acetylcysteine conjugates were detected in urine, (N-acetyl-S-(2-hydroxypropyl)-L-cysteine, N-acetyl-S-(2-oxopropyl)-L-cysteine and N-acetyl-S-(2-carboxyethyl)-L-cysteine). These accounted for 10%, 14% and 2% of the dose given to the 100 mg/kg bwt animals, respectively. Attempts to identify three other HPLC peaks were unsuccessful.

Source	:	The 1,2-Dichloropropane ICCA/HPV Consortium
Attached document	:	Attachment 5.0a.doc
Conclusion	:	Urine and exhaled carbon dioxide were the principle routes for excretion of PDC in male and female rats after single or repeated oral administration. The pathway leading to CO ₂ is quantitatively less important at higher doses. The majority of radioactivity was excreted within 24 hr, with little or no unchanged PDC present.

GLP	:	yes
Test substance	:	as prescribed by 1.1 - 1.4
Method	:	Animals and treatments Two female F344 rats (12 wk old) were administered deuterated PDC (D6-PDC, 100 mg/kg bwt) to examine the mechanism of formation of urinary metabolites. After treatment the animals were housed in glass metabolism cages and urine collected for 24 hr. The test material contained an average of 5.9 deuterium atoms, with less than 1% unlabelled material present.
Result	:	Analysis Urine samples were derivatized twice (ethereal diazomethane and N,O-bis(trimethylsilyl)trifluoroacetamide) and analysed by GC-MS. Three mercapturic acids were identified as urinary metabolites of PDC: Metabolite I 2-hydroxypropylmercapturate (containing 3 deuterium atoms); Metabolite II 2-oxopropylmercapturate (containing 3 deuterium atoms); Metabolite III 1-carboxyethylmercapturate (containing 4 deuterium atoms); Based on the number of deuterium atoms present, the authors propose that PDC undergoes oxidation, either prior to or following conjugation with glutathione to give Metabolite II and Metabolite III. Enzymatic reduction of Metabolite II gives Metabolite I.
Source	:	The 1,2-Dichloropropane ICCA/HPV Consortium
Conclusion	:	Conjugation with glutathione is an important pathway for the metabolism of PDC in vivo.

5.1.2 ACUTE INHALATION TOXICITY

Type : LC50
Value : = 2000 ppm
Species : rat

5. Toxicity

Id 78-87-5

Date 14.12.2004

Strain	: Sherman
Sex	: male/female
Number of animals	: 6
Vehicle	:
Doses	:
Exposure time	: 4 hour(s)
Method	:
Year	: 1949
GLP	: no
Test substance	: as prescribed by 1.1 - 1.4
Method	: Six male or female Sherman rats (approx. 100 - 150 g) were exposed to PDC vapor (nominal concentrations up to 2000 ppm) for 4 hr or 8 hr, then observed for a 14 day follow-up period. The test atmosphere was generated by passing air (2.5 l/min) through a fritted glass disc immersed in liquid PDC. The resulting vapour-laden stream was mixed with fresh air to produce a series (log base 2) of exposure concentrations. The reported values are nominal (based on weight of material evaporated) and not verified analytically.
Remark	: Conversion factor: 1 ppm = 4.70 mg/l
Result	: Results from a preliminary study, summarised in tabular form, indicate that there was 33-67% mortality following 4 hr exposure to 2000 ppm PDC (equivalent to 9.4 mg/l). There were 3/6 deaths in the definitive study following an 8 hr exposure to this same concentration. Thus the same extent of mortality was observed in rats exposed to PDC vapor for 4 hr or 8 hr. Since the longer exposure was not more hazardous than the shorter exposure, it is concluded that these results most likely reflect the 4 hr acute toxicity of 1,2-dichloropropane in the rat.
Source	: The 1,2-Dichloropropane ICCA/HPV Consortium
Conclusion	: The 4 hr inhalation LC50 for PDC in the rat is 2000 ppm (9.4 mg/l).
Reliability	: (2) valid with restrictions Early (pre-guideline) study, generally well documented and acceptable for assessment.
Flag	: Critical study for SIDS endpoint
25.10.2004	(172) (164)
Type	: LC50
Value	: > 2200 ppm
Species	: rat
Strain	: Sprague-Dawley
Sex	: no data
Number of animals	: 33
Vehicle	:
Doses	: 2200 ppm
Exposure time	: 7 hour(s)
Method	:
Year	:
GLP	: no
Test substance	: no data
Method	: Thirty three adult rats (bwt 150 - 200 g) were exposed once to a 2200 ppm (nominal) PDC vapour for 7 hr. The concentration of PDC in the exposure chamber was calculated from measurements of the weight of solvent

	<p>volatilised and the rate of air flow through the chamber. This was compared with the analysed content of PDC in a sample of chamber air, quantified using thermal decomposition and estimation of inorganic chloride.</p> <p>Groups of 3 -5 animals taken for necropsy on days 0, 1, 2, 4, 7, 9 and 14 days post-exposure, and subject to macroscopic evaluation. Tissue sections were prepared from adrenals, heart, liver, kidney and subject to microscopic examination. Three unexposed rats served as controls.</p>
Remark	: 1 ppm = 4.70 mg/m ³
Result	: Two rats died shortly after exposure, while the remainder survived until scheduled necropsy. (Advanced autolysis precluded microscopic evaluation of tissues from the decedents.)
	<p>Slight visceral congestion and fatty liver were the main macroscopic changes present.</p> <p>Microscopic examination of the liver revealed marked-to-moderate, midzonal-to-diffuse, fine droplet fatty degeneration with centrilobular necrosis in all animals sacrificed 24 hr post-exposure. Some necrotic liver cells were also present in 3/5 rats 48 hr post-treatment, and 1/3 rats at 4 days. Glycogen depletion was present 24-48 hr post-exposure, while deposition of hemosiderin in Kupffer cells was present from day 4 onwards. Livers of rats sacrificed 2 days after exposure to PDC showed some increase in occurrence of scattered mitotic figures.</p> <p>Fine droplets of fat were observed in convoluted tubules and thick portions of the loop of Henle of 4/5 rats at day 1 post-exposure and 2/5 on day 2, with minimal fatty change in 3/5 rats at day 7.</p> <p>The amount of fat in the adrenal cortex showed a slight-to-moderate decrease in animals necropsied immediately and 24 hr post-exposure.</p> <p>Interstitial pneumonia was present occasionally in all groups, including controls.</p>
Source	: The 1,2-Dichloropropane ICCA/HPV Consortium
Conclusion	: Under the conditions of the study, the inhalation LC50 for PDC in the rat was >2200 ppm (7 hr exposure). Treatment-related changes appeared limited primarily to liver.
Reliability	: (2) valid with restrictions Early (pre-guideline) study, generally well documented and acceptable for assessment.
Flag	: Critical study for SIDS endpoint

5. Toxicity

Id 78-87-5

Date 14.12.2004

Year	:	
GLP	:	no
Test substance	:	no data
Method	:	<p>Thirty three adult guinea pigs (bwt 600 - 800 g) were exposed to a 2200 ppm (nominal) PDC vapour for 7 hr.</p> <p>The concentration of PDC in the exposure chamber was calculated from measurements of the weight of solvent volatilised and the rate of air flow through the chamber. This was compared with the analysed content of PDC in a sample of chamber air, quantified using thermal decomposition and estimation of inorganic chloride.</p> <p>Groups of 2 -5 animals taken for necropsy on days 0, 1, 2, 4, 7, 9, 11, 14, 16 and 21 after treatment, and subject to macroscopic evaluation. Tissue sections were prepared from adrenals, heart, liver, kidney and subject to microscopic examination. Three unexposed guinea pigs served as controls.</p>
Remark	:	
Result	:	<p>1 ppm = 4.70 mg/m³</p> <p>There were no premature deaths during the study. At necropsy, many animals showed slight visceral congestion and fatty change in the liver, while the cut surface of the adrenal glands showed a hemorrhagic central portion.</p> <p>Microscopic examination revealed small-to-moderate amounts of fat in the heart, liver and kidney of exposed animals sacrificed immediately after treatment.</p> <p>Exposed animals showed a reduction in liver glycogen on day 0 and day 1 post-treatment, a normal amount at day 2 then a marked increase from day 4 onwards. Hepatocytes in affected animals were swollen with pale, vacuolated cytoplasm, especially in the centrilobular region.</p> <p>Histopathological changes in adrenal tissue included thickening, vacuolation, hemorrhage increased occurrence of mitotic figures and necrosis of the cortex during the first week post-treatment. These changes began to resolve during the second week post-exposure and adrenal tissue from two out of three guinea pigs sacrificed on day 21 appeared normal. Changes in the medulla included congestion, oedema, white cell infiltration and occasional necrotic cells up to day 7, but these tended to have resolved by day 9. Deposits of fat and hemosiderin were present in connective tissue surrounding the medulla at day 21.</p>
Source	:	
Conclusion	:	<p>The 1,2-Dichloropropane ICCA/HPV Consortium</p> <p>Under the conditions of the study, the inhalation LC50 for PDC in the guinea pig was >2200 ppm (7 hr exposure). Treatment-related changes appeared limited to primarily to the adrenal gland.</p>
Reliability	:	<p>(2) valid with restrictions</p> <p>Early (pre-guideline) study, generally well documented and acceptable for assessment.</p>

Remark : Four days after exposure, an increased sedimentation of hemosiderin was observed in von Kupffer's cells centrilobularly located. Mortality: 3/33. Sprague-Dawley were dissected and centrilobular necrosis, fatty degeneration and a decreased glycogen content in the liver were found after being exposed to 1,2-dichloropropane for 24 hours.
The animals, exposed to 1,2 dichloropropane were dissected immediately after the exposure or 7 days later. They showed no substance-caused damage to the liver.

5.1.3 ACUTE DERMAL TOXICITY

Type : LD50
 Value : = 10100 mg/kg bw
 Species : rabbit
 Strain :
 Sex :
 Number of animals :
 Vehicle :
 Doses :
 Method :
 Year : 1962
 GLP : no
 Test substance : no data

Method : PDC was applied to clipped skin of male albino rabbits (2.5 - 3.5 kg, n=4 per treatment) under occlusion for 24 hr. The animals were immobilised during exposure, then returned to their cages and observed for 14 days.

Result : An LD50 of 8.75 ml/kg bw was reported. This is equivalent to 10,100 mg/kg bw, based on a density of 1.155 g/ml [Source: MacKay et al (1993) Illustrated Handbook of Physical-Chemical Properties and Environmental Fate for Organic Chemicals, Vol III, p479]

Source : The 1,2-Dichloropropane ICCA/HPV Consortium

Conclusion : Under the conditions of the study, the dermal LD50 for PDC in male rabbits was 8.75 ml/kg bw (10100 mg/kg bw).

Reliability : (2) valid with restrictions
 Early (pre-guideline) study, generally well documented and acceptable for assessment.

Flag : Critical study for SIDS endpoint

5.3 SENSITIZATION

Type	: Mouse local lymphnode assay
Species	: mouse
Number of animals	:
Vehicle	: other: acetone olive oil
Result	: not sensitizing
Classification	:
Method	: other: OECD 429 (2002); U.S. EPA OPPTS 870.2600 (2003)
Year	: 2003

GLP	:	yes
Test substance	:	
Method	:	<p>Range-finding Test</p> <p>Selection of the upper-dose level for the definitive study was based upon results from an irritation range-finding test where 80%, 60%, 40%, 20%, or 10% v/v PDC in acetone:olive oil (AOO) was applied to each ear of female mice (1 mouse /dose) on two consecutive days. No appreciable ear swelling or erythema were noted and 80% v/v was chosen as the highest dose.</p> <p>Main study (LLNA)</p> <p>Groups of six female BALB/c mice (approximately 18 g, 8 weeks old) received topical applications (25 ul/ear, total 50 ul/mouse) of 5%, 20% or 80% propylene dichloride (PDC) in AOO on three consecutive days. A positive control group was treated with 30% a-hexyl cinnamaldehyde (HCA), a recognized skin contact allergen, diluted using AOO.</p> <p>On day 6, all mice received a 250 µl intravenous injection via the lateral tail vein containing 20 µCi of 3H-thymidine (specific activity 2Ci/mmol; Amersham code TRA310) diluted in phosphate buffered saline (PBS). Approximately five hours later, the mice were sacrificed and the auricular lymph nodes (located at bifurcation of the jugular veins) excised, combined for each mouse and placed in PBS.</p> <p>A single cell suspension of lymph node cells was prepared by gentle mechanical disaggregation using a tissue homogenizer. The cells were washed using PBS and suspended in 5% trichloroacetic acid (TCA); suspended precipitates were centrifuged and the pellets reconstituted in 1 ml of 5% TCA prior to transfer to a scintillation vial containing 10 ml of Aquasol-2 scintillation cocktail. Tubes used for suspending the pellets were rinsed using two additional 2-ml aliquots of water and the rinses were added to the scintillation vials. The radioactivity in each precipitate (representing two lymph nodes from one animal) was measured using a B-scintillation counter and reported as disintegrations per minute (dpm) per mouse.</p> <p>Interpretative criteria</p> <p>In addition to the application of statistical methods, sensitization potential was further determined by the magnitude of any lymphocyte proliferative response in relation to vehicle controls. A stimulation Index (SI) of = or > 3 (i.e. 3-fold or greater proliferation than control animals) was considered indicative of a potential for dermal sensitization.</p> <p>Statistical methods</p> <p>Comparisons of dpm values for treated vs. control groups were done by Dunnett's t-test when ANOVA results suggested differences. The alpha level at which all tests were conducted was 0.05.</p>
Result	:	<p>PDC did not demonstrate any lymph node cell proliferation response, nor any LLNA results (dpm and SI) consistent with dermal sensitization as the lymph nodes draining the area of topical application did not demonstrate a proliferative response equal to or greater than the 3x threshold. SI values were consistently around 1.0 (equivalent to vehicle</p>

	controls) at all doses tested:
	Proliferative response
	Control A (mean and SD)
	5% B
	20% C
	80% D
	Proper conduct and responsiveness of the test was confirmed in animals treated with 30% HCA (positive control group) where proliferation (SI) was 14-fold greater than that of vehicle controls.
	Because the SI values for 5, 20, and 80% PDC were all below 3, an EC3 value could not be determined. On the basis of these results, PDC did not demonstrate any contact sensitization potential.
Source	: The 1,2-Dichloropropane ICCA/HPV Consortium
Conclusion	: 1,2 dichloropropane did not stimulate proliferation of lymphocytes in auricular lymph nodes from mice treated with up to 80% PDC in AOO on 3 consecutive days. It was concluded that PDC was not a sensitizer under the conditions of this assay.
Reliability	: (1) valid without restriction GLP guideline study.
25.10.2004	(183)
Type	: Patch-Test
Species	: human
Number of animals	:
Vehicle	: petrolatum
Result	: ambiguous
Classification	:
Method	:
Year	: 1989
GLP	: no
Test substance	: no data
Method	: Subjects and symptoms The test subjects were 10 workers (painters, metal workers) with exposure to mixed solvents, including preparations containing 10-40% 1,2-dichloropropane (analysis by GLC, no details presented). Reported symptoms included itchy erythematous, oedematous lesions on the fingers and dorsa of the hands, with scaling and fissuring of the palms in 2 individuals. The patients were assessed during the period 1985-1988. 120 control subjects were included in the investigation (no further details provided).
	Patch testing Patch tests were carried out "according to internationally accepted methods" (no further details provided) using Porotest on Scanpor, with readings made according to ICDRG recommendations (no further details provided). PDC (1%, 2%, 5%, 10%, 20%) and other product constituents (resins, solvents, mineral oils, perchloroethylene, trichloroethylene) were tested in addition to the European standard series (Hermal-Trolab). Comment: no information is provided on the origin or purity of the PDC used during the challenge phase of this study.
	Statistical methods None applied (observational study).

Result	<p>: Control subjects</p> <p>No response to PDC was noted in 118 of the control subjects; slight erythema was present in the two remaining control individuals after challenge with 20% PDC in petrolatum. With the exception of a single positive reaction to methyl acrylate, no positive response was noted toward the other substances included in this study (no further details provided).</p> <p>Test s subjects</p> <p>Skin reactions were elicited in all 10 subjects after patch testing with PDC, although not all responded for all tests. Responses were reported as follows:</p> <p>1% PDC: 1 score + ; 1 score ++ ; 4 score - ; 4 not tested</p> <p>2% PDC: 5 score + ; 2 score +++ ; 3 not tested</p> <p>5% PDC: 4 score + ; 4 score ++ ; 2 score +++ ;</p> <p>10% PDC: 1 score + ; 7 score ++ ; 2 score +++ ;</p> <p>20% PDC: 4 score ++ ; 4 score +++ ; 2 not tested</p> <p>A biopsy was performed on one subject (5% challenge site; skin response = score ++). Spongiosis, oedema and early vesiculation of the epidermis was present with perivascular lymphocytic infiltrate in the dermis.</p>
Source Conclusion	<p>: The 1,2-Dichloropropane ICCA/HPV Consortium</p> <p>: The authors conclude that 1,2 dichloropropane was responsible for skin reactions observed in this group of workers. Given the dearth of methodological and results detail presented in the publication, including no information on the origin or purity of the sample used during the challenge phase, and since the structure of PDC contains no obvious chemical groups with a potential to react with cellular components, this evidence is considered equivocal.</p>
Reliability	<p>: (4) not assignable</p> <p>Short case report, limited reporting of methods and results, no information on origin/purity of test sample, unknown reliability.</p>

5.4 REPEATED DOSE TOXICITY

Type : Sub-chronic
Species : rat
Sex : male/female
Strain : Fischer 344
Route of admin. : gavage
Exposure period : 13 wk
Frequency of treatm. : 5 d/wk
Post exposure period : None
Doses : 0, 60, 125, 250, 500 or 1000 mg/kg bw/d
Control group : yes, concurrent vehicle
NOAEL : = 250 mg/kg bw
LOAEL : = 500 mg/kg bw
Method : other: standard NTP methodology
Year : 1986
GLP : yes
Test substance : as prescribed by 1.1 - 1.4

Method : Groups of 10 male and 10 female F344 rats (age 7-8 wk at start of treatment) were administered PDC (99.4% pure) in corn oil by gavage at doses of 0, 60, 125, 250, 500 or 1000 mg/kg bw/d 5 d/wk for 13 wk. The animals were group housed and observed daily for clinical signs and twice daily for mortality. Animals judged to be moribund were taken to necropsy. Each animal was given a detailed weekly examination, including palpation for tissue masses or swelling. Body weights were taken weekly.

Necropsies were performed on all surviving animals at the end of the treatment period. A comprehensive range of tissues were sampled and preserved, and those from the controls, 500 mg/kg and 1000 mg/kg groups subject to microscopic examination.

The concentration of test article in the dosing solutions was verified using GC-FID.

Result : GC analysis of the dosing solutions demonstrated that the achieved concentration was 95 - 100% of target.

All male and female rats given 1000 mg/kg bw/d and 5/10 males from the 500 mg/kg bw group died before necropsy. All animals from the other treatment groups survived until study termination. Final mean body weights were decreased 16% in male and 8% in females given 500 mg/kg bw/d.

	The liver was the only organ to be affected by treatment, with centrilobular congestion present in 5/10 males and 2/10 females given 1000 mg/kg bw/d. Hepatic fatty change and centrilobular necrosis were observed in 2/10 females from the 1000 mg/kg bw/d group.	
Source	:	The 1,2-Dichloropropane ICCA/HPV Consortium
Conclusion	:	Under the conditions of the study, the sub-chronic NOEL for PDC in the rat was 250 mg/kg bw/d, based upon mortality and lower body weight in males, and lower body weight with no histopathological involvement in females, given 500 mg/kg bw/d.
Reliability	:	(1) valid without restriction Comparable to guideline study.
Flag	:	Critical study for SIDS endpoint
25.10.2004		(186)
Type	:	Chronic
Species	:	rat
Sex	:	male/female
Strain	:	Fischer 344
Route of admin.	:	gavage
Exposure period	:	103 wk
Frequency of treatm.	:	5 d/wk
Post exposure period	:	
Doses	:	males 0, 62 or 125 mg/kg bw/d; females 0, 125 or 250 mg/kg bw/d
Control group	:	yes, concurrent vehicle
NOAEL	:	= 62 - 125 mg/kg bw
LOAEL	:	= 125 - 250 mg/kg bw
Method	:	other: standard NTP methodology
Year	:	1986
GLP	:	yes
Test substance	:	as prescribed by 1.1 - 1.4
Method	:	Methods are described in detail in Section 5.7 (Carcinogenicity).
		Samples of the following tissues were subject to histopathological evaluation:
		Integumentary system
		Respiratory system
		Haematopoietic system
		Circulatory system
		Digestive system
		Urinary system
		Endocrine system
		Reproductive system
		Nervous system
		Special sense organs
		Musculoskeletal system
		Body cavity
		Adipose tissue
		Any tissue appearing abnormal at necropsy.
Result	:	Body weight and clinical signs
		Treated animals showed a dose-related reduction in body weight. Final body weights were approx. 5% lower than control for low dose animals, and 14% and 24% lower than control in the high dose male and female groups, respectively. No clinical signs are described.
		Survival

	<p>The survival of high dose females (250 mg/kg bw/d) was significantly ($P < 0.001$) less than that of the low dose females and controls. Mortality and morbidity was especially marked at wk 94 of the study. Survival in males was comparable for all groups (78%, 84% and 82% alive at wk 103 for the control, 62 mg/kg bw/d and 125 mg/kg bw/d groups, respectively).</p> <p>Non-tumor pathology The incidence of hepatic foci of clear change (22% versus 6% in controls) and liver necrosis (focal and centrilobular combined; 18% versus 2% in controls) were increased in high dose female rats only. The incidence of other lesions in the treated animals was similar or lower than that of the controls.</p>
Source	: The 1,2-Dichloropropane ICCA/HPV Consortium
Conclusion	: Under the conditions of the study, the chronic NOEL for PDC in male rats was 62 mg/kg bw/d (based upon a reduction in final body weight observed at 125 mg/kg bw/d). The NOEL in females was 125 mg/kg bw/d (based upon lower body weight, lower survival and liver lesions present in the 250 mg/kg bw/d group).
Reliability	: (1) valid without restriction Comparable to guideline study, with restrictions.
Flag	: Critical study for SIDS endpoint
25.10.2004	(186)
Type	: Sub-acute
Species	: mouse
Sex	: male/female
Strain	: B6C3F1
Route of admin.	: gavage
Exposure period	: 14 days
Frequency of treatm.	: Consecutive days
Post exposure period	: One day
Doses	: 0, 125, 250, 500, 1000 or 2000 mg/kg bw/d
Control group	: yes, concurrent vehicle
NOAEL	: = 250 mg/kg bw
LOAEL	: = 125 mg/kg bw
Method	: other: standard NTP methodology
Year	: 1986
GLP	: yes
Test substance	: as prescribed by 1.1 - 1.4
Method	: Groups of 5 male and 5 female B6C3F1 mice (age 6 wk at start of treatment) were administered PDC (99.4% pure) in corn oil by gavage at doses of 0, 125, 250, 500, 1000 or 2000 mg/kg bw/d for 14 consecutive days, followed by one day of observation. The animals were group housed (5/sex/cage) and observed twice daily for mortality.
	Necropsies were performed on all animals (macroscopic observations only, no histopathology included).
	The concentration of test article in the dosing solutions was verified using GC-FID.
Result	: GC analysis of the dosing solutions demonstrated that the achieved concentration was 95 - 100% of target.
	All male mice receiving 1000 or 2000 mg/kg bw/d and 3/5 given 500 mg/kg bw/d died during the study. All females from the 2000 mg/kg bw/d group, and 4/5 from the 1000 mg/kg bw/d

	group also died pre-study termination.
	Final mean body weight for the surviving mice was unaffected by treatment.
	The renal medullae were red in all mice of both sexes from the 2000 mg/kg bw/d group, the majority of males given 500 mg/kg and the majority of females given 1000 mg/kg bw/d. This change was also present in single females from all other dose groups.
Source	No other compound-related effects were observed at necropsy.
Conclusion	: The 1,2-Dichloropropane ICCA/HPV Consortium
	: Under the conditions of the study, the sub-acute NOEL for PDC in male mice was 250 mg/kg bw/d. No NOEL was established for female mice (LOEL 125 mg/kg bw/d).
Reliability	: (1) valid without restriction
	Comparable to guideline study.

	Reproductive system	
	Nervous system	
	Special sense organs	
	Musculoskeletal system	
	Body cavity	
	Adipose tissue	
	Any tissue appearing abnormal at necropsy.	
Result	: Body weight and clinical signs	
	Mean body weights of treated and vehicle control animals were comparable, and no compound-related clinical signs were noted.	
	Survival	
	The survival of high dose females (250 mg/kg bwt/d) was significantly ($P < 0.035$) less than that of the low dose females and controls, with 70%, 58% and 52% of the control, low and high dose animals surviving to termination. Survival	

	in males was comparable for all groups (70%, 66% and 70% alive at wk 103 for the control, 125 mg/kg bwt/d and 250 mg/kg bwt/d groups, respectively). The report notes that the lowered survival in female mice was related to an increased incidence of reproductive tract infections in animals which died before the end of the study (45% of controls versus 64% of the low and high dose females that died during the study).
	Non-tumor pathology Hepatocytomegaly (6%, 10% and 30% for control, low dose and high dose animals, respectively) and hepatic focal necrosis (4%, 10% and 20%) were seen in male mice only.
	Acanthosis of the surface epithelium of the forestomach occurred at increased incidence in high dose males (0%, 0%, 4%) and both groups of females (0%, 10%, 8%).
	Suppurative inflammation (affecting ovary, uterus or multiple organs, and a presumed consequence of reproductive tract infection) was found in 5/11 control, 9/14 low dose and 14/22 high dose females that died before the end of the study.
Source	: The 1,2-Dichloropropane ICCA/HPV Consortium
Conclusion	: Under the conditions of the study, the chronic LOAEL for PDC in mice was 125 mg/kg bw/d (based upon liver lesions in male mice and acanthosis of the stomach in females). The NOAEL was <125 mg/kg bwt/d.
Reliability	: (1) valid without restriction Comparable to guideline study.

Species	: rat
Sex	: male/female
Strain	: Fischer 344
Route of admin.	: inhalation
Exposure period	: 13 wk
Frequency of treatm.	: 6 hr/d, 5 d/wk
Post exposure period	:
Doses	: 0, 15, 50 or 150 ppm (0, 0.068, 0.225 or 0.675 mg/l)
Control group	: yes, concurrent vehicle
NOAEL	: = 15 ppm
Method	:
Year	: 1988
GLP	: yes
Test substance	: other TS: 99.4% purity
Method	: Animals and treatments Male and female F344 rats (n = 10 per group, age 7-8 wk at start of treatment) were exposed whole body to 0, 15, 50 or 150 ppm PDC vapor (0, 0.068, 0.225 or 0.675 mg/l) 6 hr/d, 5 d/wk for 13 wk. The test atmosphere was generated by passing heated air (50 degrees) through a J-tube containing a measured amount of PDC. The chamber volume was 4100 l (stainless steel and glass construction; 1 chamber per exposure group) and total airflow was 800 l/min (12 air changes/hr). The distribution of PDC within the chamber was determined 1-2 times/hr at 9 sampling points using a MIRAN 1A infrared spectrometer.

Observations

Animals were examined after each exposure period for clinical signs or indications of overt toxicity.

Haematology

Packed cell volume (PCV), red blood cell counts (RBC), haemoglobin (HGB), white blood cell counts (WBC), mean red cell volume (MCV), mean red cell haemoglobin (MCH), mean red cell haemoglobin concentration (MCHC), platelet counts (PLAT) and differential white cell counts were determined approx. 2 wk prior to study termination using blood collected by orbital sinus puncture.

Clinical chemistry

Total bilirubin (TBILI), serum glutamic pyruvic transaminase (SGOT), serum glutamic oxaloacetic transaminase (SGPT), alkaline phosphatase (AP), urea nitrogen (UN) and glucose (GLUC) were determined on blood (cervical vein) collected at necropsy. Red blood cell and plasma cholinesterase were quantified on blood collected by orbital sinus bleed approx. 2 wk prior to sacrifice.

Urine analysis

Specific gravity (refractive index; American Optical Co), pH, glucose, ketones, bilirubin, occult blood and protein (Chemstrip 7, Bio-Dynamics) were determined approx. 2 wk prior to sacrifice.

Necropsy

Rats were sacrificed on the day after the last exposure following an overnight fast. The eyes and internal organs were subject to macroscopic examination, and the weights of the brain, heart, liver, kidneys, thymus and testes recorded. Approx. 50 tissues were sampled, preserved and processed for microscopic examination (haematoxylin and eosin).

Statistical methods

Clinical chemistry, haematology, urine analysis and organ weights were analysed using Bartlett's test for equality of variances, followed by parametric or non-parametric ANOVA with Dunnett's test or the Wilcoxon Rank-Sum test with Bonferroni's correction for multiple comparisons. The final interpretation of the results considered whether an exposure-response relationship was apparent in the data since a high occurrence of Type I (false positive) errors would be anticipated due to the large number of statistical comparisons that were included in this study.

Result

: IR analysis demonstrated that the mean concentration of PDC within the chamber (SD in brackets) was 0, 15(1), 50(3) or 151(3) ppm.

Clinical observations and body weight

One male rat from the 15 ppm group died on day 81 from haemorrhagic cystitis; this was considered a spontaneous event by the study pathologist. No other clinical or overt signs of toxicity were recorded in any of the treated animals during the 90 d exposure period.

Body weights for high dose animals were significantly decreased throughout the study (females decreased 7% at termination, males 10%), with a smaller (non-significant)

decrease apparent in mid-dose animals from wk 2 onwards (4-8% decrease at termination).

Haematology and urine analysis

There were no toxicologically or statistically significant changes in haematological or urine parameters in any of the treatment groups.

Clinical chemistry

SGPT values from all treated females were decreased 25-31% relative to controls, while SGOT from females exposed to 15 or 50 ppm PDC were decreased 18-21% (no effect in high dose animals). Serum glucose was decreased 22% in mid dose males only. None of these changes were considered toxicologically significant by the study authors.

Necropsy findings

Several slight but statistically significant effects in organ weights were noted in rats exposed to 50 or 150 ppm PDC for 13 wk i.e. relative brain weight increased 8% and relative heart weight increased 6% in mid dose males, absolute brain weight decreased 3% in high dose females. A qualitative reduction in the amount of abdominal adipose tissue was also noted in some high dose males. These changes were considered of negligible toxicological relevance by the study authors (secondary to lower bwt).

Histopathology

Histopathological effects were confined to the upper respiratory tract. Very slight or slight degeneration of the olfactory mucosa in the anterior portion of the nasal cavity was noted for all rats exposed to 50 or 150 ppm PDC (no effect at 15 ppm). Very slight or slight hyperplasia of the respiratory mucosa was also present in the majority of rats (both sexes) exposed to 50 or 150 ppm PDC, with very slight hyperplasia detected in around one quarter of the low dose group. This hyperplasia was focally restricted to the anterior portion of the nasal tissues and considered by the study pathologist to be an adaptive, protective response. Chronic inflammation of nasal tissue was present in all groups, including controls, but was slightly more prevalent in high dose rats of both sexes.

Source Conclusion

- : The 1,2-Dichloropropane ICCA/HPV Consortium
- : Minimal toxicological effects were recorded in male and female F344 rats following whole body exposure to 0, 15, 50 or 150 ppm PDC for 13 wk. Treatment related effects were limited to a minor reduction in body weight (NOAEL = 15 ppm), and very slight hyplasia of the nasal respiratory epithelium considered to be an adaptive/protective response by the study authors (NOAEL of 15 ppm).

Reliability

- : (1) valid without restriction
- : Comparable to guideline study.
- : Critical study for SIDS endpoint

Result	<p>: IR analysis demonstrated that the mean concentration of PDC within the chamber (SD in brackets) was 0, 151(3), 502(7) or 1003(8) ppm.</p> <p>Clinical observations and body weight</p> <p>No clinical signs or evidence of overt toxicity were recorded in any of the treated animals, while body weights were indistinguishable from those of the controls.</p> <p>Haematology</p> <p>Analysis of blood samples collected 2 wk prior to study termination showed that RBC were significantly decreased in rabbits exposed to 150 ppm (10% decrease, males only), 500 ppm (both sexes, approx. 15-20%) or 1000 ppm (both sexes, approx. 20-25%) PDC vapor. HGB was decreased (both sexes) in</p>

mid (10-13%) and high (14-16%) dose rabbits. PCV was decreased (both sexes) in mid (11-15%) and high (17%) dose rabbits. MCV and MCH increased (both sexes) in a non-significant but apparently dose-related manner.

Essentially similar changes in RBC, HGB and PCV were present in blood samples collected at study termination. In addition, the number of nucleated erythrocytes was non-significantly increased in males exposed to 1000 ppm PDC, while the percentage of reticulocytes (regenerative response) was increased significantly in mid (approx. 2-fold) and high (3-4 fold) dose animals of both sexes. MCV and MCH were again increased in all treated animals.

Overall, these findings were consistent with regenerative macrocytic normochromic anemia.

Clinical chemistry

No treatment related changes were recorded.

Necropsy findings

Absolute liver weights from mid and high dose males were significantly increased by approx. 25-30%, and relative liver weight significantly increased by approx. 20%.

Supplemental information presented in the study report demonstrates that absolute liver weights values from treated animals (107.9- 122.0 g) were within the historical range for control male rabbits from the laboratory conducting this study (93.8 - 130.3 g), while the controls (93.8 g) were at the lower limit of the historical data. The authors conclude that these liver weight changes were not indicative of a treatment related effect. No other organ weight changes or gross lesions were present.

Histopathology

Bone marrow hyperplasia (regenerative response) was present in some rabbits exposed to 500 or 1000 ppm PDC vapor (NOAEL = 150 ppm), with a qualitative increase in haemosiderin-laden macrophages noted in bone marrow from high dose animals. Minimal degeneration of olfactory epithelium occurred in nasal tissue from all groups, including the controls, however the prevalence in high dose males (5/7 affected, versus 2/7 controls) was considered suggestive of a treatment-related effect by the study authors (NOAEL = 500 ppm). No other treatment related histopathological changes were observed.

Source Conclusion

- : The 1,2-Dichloropropane ICCA/HPV Consortium
- : Minimal toxicological effects were recorded in male and female NZW rabbits following whole body exposure to 0, 150, 500 or 1000 ppm PDC for 13 wk. Treatment related, toxicologically significant changes were limited to alterations in red cell parameters (decreased RBC, HGB, PCV) in male rabbits exposed to 150-1000 PDC for 13 wk (LOAEL = 150 ppm), and in females exposed to 500 or 1000 ppm over the same period of time (NOAEL = 150 ppm). The overall pattern of changes was consistent with a regenerative macrocytic normochromic anemia. Minimal degeneration of olfactory epithelium in high dose males (NOAEL = 500 ppm; females unaffected) was also observed.

Date 14.12.2004

25.10.2004

(187)

Type : Sub-acute
Species : rat
Sex : male/female
Strain : Fischer 344
Route of admin. : gavage
Exposure period : 14 days
Frequency of treatm. : Consecutive days
Post exposure period : One day
Doses : 0, 125, 250, 500, 1000 or 2000 mg/kg bw/d
Control group : yes, concurrent vehicle
NOAEL : = 500 mg/kg bw
LOAEL : = 1000 mg/kg bw
Method : other: standard NTP methodology
Year : 1986
GLP : yes
Test substance : as prescribed by 1.1 - 1.4

Method : Groups of 5 male and 5 female F344 rats (age 6 wk at start of treatment) were administered PDC (99.4% pure) in corn oil by gavage at doses of 0, 125, 250, 500, 1000 or 2000 mg/kg bw/d for 14 consecutive days, followed by one day of observation. The animals were group housed (5/sex/cage) and observed twice daily for mortality.

Necropsies were performed on all animals (macroscopic observations only, no histopathology).

The concentration of test article in the dosing solutions was verified using GC-FID.

Result : GC analysis of the dosing solutions demonstrated that the achieved concentration was 95 - 100% of target.

All rats given 2000 mg/kg bw died during the study, along with a single male from the 125 mg/kg bw/d group.

Final mean body weight was decreased 14-15% in animals given 1000 mg/kg bw/d relative to the controls.

The renal medullae were red in 4/5 males and 5/5 females given 2000 mg/kg bw/d but not in rats from the lower treatment groups.

Source : The 1,2-Dichloropropane ICCA/HPV Consortium
Conclusion : Under the conditions of the study, the sub-acute NOEL for PDC in male and female rats was 500 mg/kg bw/d.

Reliability : (1) valid without restriction

(174)

Type :
Species : rat
Sex : male
Strain : Sprague-Dawley
Route of admin. : gavage
Exposure period : 5 and 10 days
Frequency of treatm. : daily
Post exposure period :
Doses : 100, 250, 500 and 1000 mg/kg body weight/day
Control group : yes, concurrent vehicle
LOAEL : = 100 mg/kg bw
Method : other: Repeated Dose Toxicity
Year : 1989
GLP : no data
Test substance : other TS: purity = 99 %

Remark : Depending on dosage, animal body weight was reduced (no specific information) and sedation was detected. The highest dose was given for 5 days resulting in a significant ($p \leq 0.05$) increase of sorbitol dehydrogenase transferase reactivity and alanine aminotransferase reactivity as well as urea content in the blood. After 10 days, only increase of urea content persisted. Doses given above 100 mg/kg, after days 5 and 10, the content of microsomal cytochrom P-450 in the liver decreased significantly ($p \leq 0.05$). After 5 days using ≥ 250 mg/kg, the non-protein-sulphydryl-content in the liver was significantly ($p \leq 0.05$) decreased (dose-related). After 10 days of dosing, only the group with highest dose administered showed a significant ($p \leq 0.05$) reduction in NPSH. After days 5 and 10 using ≥ 250 mg/kg, the non-protein-sulphydryl-content in the kidney was significantly ($p \leq 0.05$) increased. After 5 days of treatment, histopathological changes were found only in the liver. Jaundice was diagnosed, characterized by necrosis of the centrilobular hepatocytes, inflammatory cell infiltration and proliferation of fibroblasts. The changes appeared in all animals treated with 1000 mg/kg. In the group tested with 250 and 500 mg/kg, less than 50% of the animals showed changes (no further information). 5 days later symptoms persisted only in the two groups receiving highest doses but in a less intensive form. After days 5 and 10 of dosing, a hemolytic anemia was diagnosed in the kidney; 6 - 8 animals/dosage and control group.

Method	:	other: Repeated Dose Toxicity	
Year	:	1989	
GLP	:	no data	
Test substance	:	other TS: purity = 99 %	
Remark	:	The body weight gain was decreased significantly ($p \leq 0.05$) at concentrations ≥ 100 mg/kg (dose related). All animals of the 750 mg/kg dosage group died or were killed moribund after the first 2 weeks of treatment. Mortality in the 500 mg/kg dosage group was approximately 60 %. In the 750 mg/kg dosage group the following histopathological changes appeared: light hepatitis, hemosiderosis in the spleen, vacuolization of medulla, lipidosis of the renal cortex, reduced sperm count and appearance of degenerated spermatogonia in the epididymis. Doses of 1,2-dichloropropane induce hemolytic anemia. Animals treated with 250 and 500 mg/kg, showed significantly ($p \leq 0.05$) decreased hemoglobin and hematocrit in serum; histopathologic examination showed hemosiderosis and hyperplasia of the erythropoietic elements in the spleen for most animals in all dosage groups. Only animals from the 500 mg/kg dosage group showed histopathologic changes in the liver (periportal vacuolization and fibroplasia). Relative weight of liver and spleen in dosage groups 250 and 500 mg/kg and relative weight of kidney in dosage group 500 mg/kg were significantly ($p \leq 0.05$) increased; 15 - 16 animals/dosage and control group.

Test substance : other TS: purity = 99.4 %

Remark : 50 animals/sex/dosage and control group
Result : Body weight gain was decreased (dose related) in male and female animals. Mortality for females was increased significantly ($p < 0.001$) in the 250 mg/kg dosage group (26 % control, 14 % 125 mg/kg, 68 % 250 mg/kg). For females in the high dosage group an increased incidence of focal and centrilobular liver necrosis (2/50, 1/50 or 12/50), foam cell foci (3/50, 5/50 or 11/50) and a light hemosiderosis in the spleen was observed. All other tumors relating to type, incidence and time of formation were equal to the control group. No substance related, histopathologic, non-neoplastic changes appeared other than the ones mentioned above. Female animals were diagnosed more often with mammary carcinoma (dose related) (1/50, 2/50 and 5/50; historic control of the research institute : 3/50).

GLP : yes
Test substance : as prescribed by 1.1 - 1.4

Remark : All rabbits in the two high dose groups and one rabbit in the 250 mg/kg-dose group died or were killed moribund during the test period. The animals of the high dose group, before dying, showed lethargy and ataxy. All treated animals showed a decreased gain of body weight. Necrosis of the liver was detected in all dead animals per above, given 500 and 1000 mg/kg. Some of these animals suffered light anemia and dilation of renal tubuli was prevalent; two animals/dosage and control group.

Species : dog
Sex : no data
Strain : no data
Route of admin. : inhalation
Exposure period : up to 128 exposures
Frequency of treatm. : 7 hours/day, 5 days/week
Post exposure period : no
Doses : 4400 mg/m³
Control group : no data specified
Method : other: Repeated Dose Toxicity
Year : 1946
GLP : no data
Test substance : no data

Remark : Mortality: 4/9.
During dosing period, 3 dogs died between exposure 27 and 28 and 1 dog died after exposure 96. Fatty degeneration of the liver and the convoluted renal tubuli was detected in all animals that died. In addition, one dog was diagnosed with centrilobular congestion including atrophy and necrosis in the liver cells and 2 dogs were diagnosed with fatty degeneration of the heart and lipoid atrophy in the renal cortex. One dog dying after 28 exposures was observed with congestion, atrophy and focal necrosis in zona reticularis of the adrenal gland. Some of the surviving 5 dogs were killed after 55 single exposures and the rest after 128 exposures. These 5 dogs showed no histopathological differences compared with the control group; 9 dogs/exposure group.

Result	:	Rats, guinea pigs and dogs received from 128 to 140 seven-hour inhalation exposures. No ill effects were observed that could be attributed to the exposures except for decreased weight gain in the rats. Histological examination showed no changes specifically attributable to 1,2-dichloropropane. There was a heavy mortality rate among mice exposed to 400 ppm of 1,2-dichloropropane. Hepatomas was found in 3 animals of the susceptible C3H strain, which were histologically similar to mice repeatedly exposed to carbon tetrachloride.

5.5 GENETIC TOXICITY 'IN VITRO'

5. Toxicity

Id 78-87-5

Date 14.12.2004

Type : Bacterial reverse mutation assay
System of testing : Salmonella typhimurium TA98, TA1537, TA100 and TA1535
Test concentration : 0 (DMSO), 33, 100, 333, 1000 and 2000 ug/plate
Cycotoxic concentr. : > 2000 ug/plate
Metabolic activation : with and without
Result : negative
Method : other: liquid preincubation method
Year : 1986
GLP : no data
Test substance : as prescribed by 1.1 - 1.4

Method : PDC was dissolved in DMSO and incubated with the tester strains in suspension culture for 20 min prior to the addition of soft agar and plating-out. Exogenous metabolic activation was provided by liver S-9 preparations from Arochlor-1254 induced rats and hamsters. Each concentration was tested in triplicate, and the entire study run twice.

Result : There was no increase in number of revertants in any of the tester strains either in the absence or presence of rat or hamster S-9 fraction.

Source : The 1,2-Dichloropropane ICCA/HPV Consortium

Conclusion : PDC was not mutagenic to Salmonella typhimurium TA98, TA1537, TA100 or TA1535 in the presence or absence of S-9.

Reliability : (2) valid with restrictions
Comparable to guideline study.

Flag : Critical study for SIDS endpoint

25.10.2004

(186)

Type : Ames test
System of testing : Salmonella typhimurium TA98, TA1537, TA100 and TA1535
Test concentration : 0 (DMSO), 31.5, 100, 315, 1000 and 3150 nl/plate
Cycotoxic concentr. : >3150 nl/plate
Metabolic activation : with and without
Result : negative
Method : other: Ames et al. (1975) Mut Res 31, 347 - 364.
Year : 1979
GLP : no
Test substance : no data

Method : PDC (aqueous, 31.5 - 3150 nl/plate) was tested using a plate incorporation method in two series of experiments in the presence or absence of S9 from Arochlor 1254-treated rats. There were two plates per concentration. Benzo(a)pyrene and MNNG were used as positive control substances in the absence of S9, and benzo(a)pyrene, 2-aminoanthracene and 3MC as positive controls in the presence of S9.

In a third series of tests, mutagenicity of PDC (3.15 - 3150 nl/plate; +S9) was evaluated in the presence of glutathione supplementation (8 mg/plate).

Result : A satisfactory response was obtained with the positive control substances.

No mutagenic response was obtained with PDC, both in the absence or presence of S9. Glutathione supplementation was without effect.

Source : The 1,2-Dichloropropane ICCA/HPV Consortium

Conclusion : PDC was not mutagenic to Salmonella typhimurium TA 98, TA 1537, TA 100 or TA 1535 when tested using a plate incorporation method in the presence or absence of S9.

Reliability : (2) valid with restrictions
Study well documented, meets generally accepted scientific

5. Toxicity

Id 78-87-5

Date 14.12.2004

Flag 25.10.2004	: principles, acceptable for assessment. : Critical study for SIDS endpoint	(194)
Type	: Ames test	
System of testing	: Salmonella typhimurium TA98, TA1537, TA100 and TA1535	
Test concentration	: vapour exposure: 0.3- 10 ml PDC placed in a 20 l dessicator and incubated with poured plates for 4 hr.	
Cycotoxic concentr.	: greater than maximum tested	
Metabolic activation	: with and without	
Result	: negative	
Method	: other: Ames et al. (1975) Mut Res 31, 347 - 364.	
Year	:	
GLP	: no	
Test substance	: no data	
Method	<p>: Poured plates, containing tester strain, cofactors and with or without S9 fraction from Arochlor 1254-induced rats, were placed in a 20 l dessicator along with 0.3 - 10 ml PDC. Dichloroethane (3 ml) was used as positive control in the presence and absence of S9.</p> <p>A third series of plates were supplemented with 8 mg glutathione.</p> <p>After 4 hr incubation at 37 degrees C the plates were removed from the dessicator and incubated for a further 3 days in the dark.</p>	
Result	<p>: Dichloroethane was not mutagenic in the absence of S9 mix, but a clear positive response was obtained in TA 100 and TA 1535 in the presence of S9.</p> <p>No mutagenic response was obtained with PDC, both in the absence or presence of S9.</p>	
Source	Glutathione supplementation was without effect.	
Conclusion	<p>: The 1,2-Dichloropropane ICCA/HPV Consortium</p> <p>: PDC vapour was not mutagenic to Salmonella typhimurium TA 98, TA 1537, TA 100 or TA 1535 when tested in a closed system in the presence or absence of S9.</p>	
Reliability	<p>: (2) valid with restrictions</p> <p>Study well documented, meets generally accepted scientific principles, acceptable for assessment.</p>	
Flag 25.10.2004	: Critical study for SIDS endpoint	(194)
Type	: Ames test	
System of testing	: Salmonella typhimurium TA98, TA1537, TA100 and TA1535	
Test concentration	: 10-10000 ug/plate; 100-1500 ug/plate	
Cycotoxic concentr.	:	
Metabolic activation	: with and without	
Result	: ambiguous	
Method	:	
Year	: 1983	
GLP	: no data	
Test substance	: as prescribed by 1.1 - 1.4	
Method	<p>: The mutagenic potential of 1,2-dichloropropane was investigated in two laboratories (Case Warren Western Reserve, CWR; EG&G Mason, EGG) using a preincubation protocol. Hepatic S-9 was prepared from male SD rats (RL) and male Syrian hamster after induction with Arochlor 1254.</p>	

The report notes that results were interpreted in an ad hoc manner by each testing laboratory and by NTP personnel. The publication describes that a positive result was indicated by a "reproducible, dose-related increase, whether it be two-fold over background or not. "Statistical analysis was applied subsequently to data considered positive.

Remark

- 2-Aminoanthracene (all strains, plus rat and hamster S9), 4-nitro-o-phenylenediamine (TA98, -S9), sodium azide (TA100 and TA1535, -S9) and 9-aminoacridine (TA1537, -S9) were used as positive control.
- : Although the number of revertants was increased in TA1535 and TA100 in the absence of S9, it is clear that the magnitude of this effect was always less than two-fold background.

Maximal increase in TA1535 over control:
56% at 1000 ug/plate (lab CWR)
75% at 3333 ug/plate (lab EEG)

Maximal increase in TA100 over control:
44% at 3333 ug/plate (lab CWR)
80% at 1500 ug/plate (lab EEG)

Result

- The results were incorrectly presented in the publications summary table as positive. The data in the appendix does not demonstrate a mutagenic response (less than a 2-fold increase). The data were reviewed by the Swiss CA and the UK CA at SIAM 17 and were determined to be negative.
- : No mutagenic activity was reported by either laboratory in TA98 or TA1537 at dose levels up to 3,333 ug/plate in the presence or absence of either source of S9.

PDC was without effect on the number of revertants recorded by either laboratory when tested using TA98 or TA100 in the presence of rat or hamster S9.

In the absence of S9, an apparent weak dose-response relationship was observed in TA1535:

	CWR	EGG
0 (DMSO)	16	25
100		24
333		31
750		37
1,000	20	39
1,500		33
1,667	26	
3,333	28	
6,667	18	
10,000	10	

In the absence of S9, an apparent weak dose-response relationship was observed in TA100:

	CWR	EGG
0 (DMSO)	172	123
100		107
333		141
750		154

25.10.2004			(196)
Type	:	Mouse lymphoma assay	
System of testing	:	L5178Y	
Test concentration	:	62.5-1000 nl/ml; 62.5-1000 nl/ml; 100-1000 nl/ml;	
Cycotoxic concentr.	:	>800 nl/ml (above limit of solubility in test media)	
Metabolic activation	:	without	
Result	:	negative	
Method	:	other: TK+/- Test	
Year	:	1988	
GLP	:	no data	
Test substance	:	no data	
Remark	:	1,2-Dichloropropane was not very toxic in the absence of rat S9 (except when the solubility limit was visibly exceeded ie 1000 nl/ml) and was evaluated by the authors as nonmutagenic	

	to L5178Y cells.	
	The authors comment that three trials were performed because weak mutagenic activity was suggested by a 1.5-fold increase in MF for the highest soluble dose of 750 nl/ml in the second trial. The third trial, however, yielded no response for doses up to 800 nl/ml and confirmed the lack of response obtained in trial 1.

Metabolic activation	: with	
Result	: positive	
Method	: other: TK+/- Test	
Year	: 1988	
GLP	: no data	
Test substance	: no data	
Remark	: The mutagenic potential of PDC in the presence of male rat Arochlor 1254-induced S9 was investigated in two trials using concentration ranges of 0-100 nl/ml in the first and 0-80 nl/ml in the second. When discussing these results, the authors comment that the first trial did not include a toxic treatment suitable for analysis, but that the highest assayed dose of 50 nl/ml (65% relative total growth; RTG) induced a 2.3-fold increase in mutation frequency. The mutant colony count was clearly elevated. The next highest dose of 100 nl/ml was lethal. A different batch of S9, which appeared to be more active, was used in the second trial. A dose-related increase in MF was obtained over the 10-80 nl/ml dose range, with 80 nl/ml being highly toxic (6% RTG) and causing a 10-fold increase in MF. They concluded that S9 activation was clearly therefore essential to the mutagenic activity of 1,2-dichloropropane. The increase in mutant frequency was due primarily to the induction of small colony mutants.

5.6 GENETIC TOXICITY 'IN VIVO'

Type : Micronucleus assay
Species : mouse
Sex : male
Strain : CD-1
Route of admin. : gavage
Exposure period : 48 hr
Doses : 0, 150, 300 or 600 mg/kg bwt/d
Result : negative
Method : EPA OPPTS 870.5395
Year : 2003
GLP : yes
Test substance : as prescribed by 1.1 - 1.4

Method : Range-finding Test:
Selection of the high-dose level for the definitive study was based upon results from a range-finding test where male and female mice (4/group) were administered up to 2000 mg/kg/day 1,2 dichloropropane by oral gavage in corn oil on two consecutive days. The animals were observed for 72 hr after the second dose, and decedents were subject to necropsy in an effort to determine the cause of death. Substantial drops in body temperature occurred 2 hrs after dosing in animals receiving 1000 mg/kg/day and higher doses and all mice at these doses died prior to the end of the observation period.

Micronucleus Test:

Groups of six male CD-1 mice (approximately 32g, 9 weeks old) were given PDC (0, 150, 300, and 600 mg/kg) by oral gavage in corn oil on two consecutive days. Clinical observations and body temperature were monitored prior to dosing, 2 and 5 hrs post dosing and prior to sacrifice. Only males were used in this assay since there was no substantial difference in toxicity between sexes in the range-finding test.

Cyclophosphamide (120 mg/kg bwt, gavage, approx. 24 hr before sacrifice) was used as positive control substance.

Animals (6/dose) were sacrificed 24 hours after the second treatment, and femoral bone marrow collected to evaluate the incidence of micronuclei (MN) in polychromatic erythrocytes (2000 PCE/animal). The proportion of PCE among erythrocytes in the bone marrow was estimated by examining 200 erythrocytes/animal.

	<p>Statistics</p> <p>The raw data on the counts of MN -PCE for each animal were first transformed by adding one (1) to each count and then taking the natural log of the adjusted number. The transformed MN -PCE data and the data on percent PCE were analyzed separately by one-way ANOVA (Winer, B. J. (1971), Statistical Principles in Experimental Design (2nd Edition), McGraw-Hill, New York, New York). Pairwise comparisons of treated vs. control groups were done, if the dose effect was significant, by Dunnett's t-test, one-sided (upper) for MN-PCE and two-sided for the percent PCE (Winer 1971). Linear dose-related trend tests were performed only if any of the pairwise comparisons yielded significant differences. The alpha level at which all tests were conducted was 0.05.</p>
Remark	: Section 5.0 (Toxicokinetics) demonstrates widespread distribution of PDC within the body, confirming contact with the target tissue in this study.
Result	: All animals survived until the end of the observation period. Incoordination was observed in one mouse from the high-dose group. A uniform drop in body temperature (approx. 2°C) occurred 2 hrs postdosing in the high-dose animals.
	<p>There was no statistically significant increase in the frequencies of MN -PCE in groups treated with PDC when compared to the negative controls. In contrast, a significant increase in the frequency of MN -PCE was recorded in the positive control group.</p> <p>The mean proportion of PCE among bone marrow erythrocytes (200/animal) was unaffected by exposure to the test material while the positive control treatment significantly reduced this value.</p>
Source	: The 1,2-Dichloropropane ICCA/HPV Consortium
Conclusion	: 1,2 dichloropropane was negative for the induction of micronuclei in this test system under the experimental conditions used.
Reliability	: (1) valid without restriction GLP guideline study.
Flag	: Critical study for SIDS endpoint
25.10.2004	(209)
Type	: Dominant lethal assay
Species	: rat
Sex	: male
Strain	: Sprague-Dawley
Route of admin.	: drinking water
Exposure period	: 14 wk
Doses	: 0, 0.024%, 0.10% or 0.24% (equivalent to 0, 28, 91 or 162 mg/kg bwt/d)
Result	: negative
Method	: other: 40 CFR 789.4700
Year	: 1989
GLP	: yes
Test substance	: as prescribed by 1.1 - 1.4
Method	: <p>Animals and treatments</p> <p>PDC was administered in drinking water (0, 0.024%, 0.10% or 0.24%) to groups of 30 male SD rats (age 4 wk) for at least 13 wk as part of the breeding phase of a reproduction study (reported in Section 5.8.3). Treatment then ceased, and 2 days later each male was co-housed with two naive females/wk</p>

for 2 wk.

The females were sacrificed by carbon dioxide inhalation approx. 14 days from the middle of their respective breeding period, and the numbers of corpora lutea, implantations and resorptions were recorded. No separate classification of early or late resorptions was performed. The uteri of apparently non-pregnant animals were stained with sodium sulphide solution (10%) and examined for evidence of early resorption sites.

A positive control group of 30 males received cyclophosphamide (100 mg/kg bwt in saline, by gavage) 48 hr prior to mating.

GC analysis showed that the test material was 99.9% pure. Stability testing demonstrated no degradation of aqueous solutions of PDC over 8 days. Based on these findings the experimental solutions were mixed and changed at least once per week, and analysed (GC) on at least 3 occasions prior to mating.

Statistics

Body weights were evaluated using Bartlett's test for equality of variances, followed by parametric or non-parametric ANOVA. If results of the ANOVA were positive, a Dunnett's test or Wilcoxon Rank-Sum test was performed. Fertility indices were analysed by the Fisher exact probability test. The numbers of corpora lutea were analysed using non-parametric ANOVA followed by the Wilcoxon Rank-Sum test. Pre-implantation losses and resorption rates were analysed by the Wilcoxon test.

Interpretation of findings

Final interpretation of the results considered statistical analyses along with other factors such as historical data, dose-response relationships and whether the findings were biologically significant in the light of other toxicological and pathological findings. This appears scientifically acceptable since a high level of Type I (false positive) errors would be anticipated as a consequence of the large number of statistical comparisons that were included in the study.

Result

: General

Analysis of drinking water showed that the achieved concentration was 88%, 98% and 100% of nominal for the low, mid and high exposure groups, respectively (mean of 3 determinations).

In-life observations

There were no significant clinical effects noted in any treatment group during the in-life phase, however two animals from the low dose group died during the pre-breeding phase (test days 56 and 101; deaths ascribed to renal failure unrelated to treatment). Body weights for the high dose males were significantly decreased from day 8 of the study, while values for mid-dose animals were numerically (but not significantly) lower than control. Water consumption was decreased in a treatment-related manner (decreased by approx. 40-50%, 22% and 10% for the high, mid and low dose groups, respectively), and food intake lowered in high dose animals during the first week of the test.

Seven of the 30 positive control group died, and one was sacrificed in a moribund state, during the breeding phase. Body weights and food and water consumption for these cyclophosphamide-treated animals were comparable to control values.

Received dose

Based upon body weight and water intake data, weekly average received doses were calculated as 0, 28.0, 90.7 and 162.1 mg/kg bwt/day for the 0%, 0.024%, 0.10% and 0.24% groups, respectively.

Mating and fertility indices

Mating performance and conception indices among treated males was comparable to control, ranging from 96.4% to 100%. These fertility parameters for cyclophosphamide-treated males were decreased significantly.

The number of corpora lutea from females mated with low and high dose was significantly increased during the first week of breeding, while the number of implantations for the second week of breeding was significantly lower in females mated with mid dose males. These differences appear consistent with normal biological variability rather than any treatment-related effect. The number of pre-implantation losses was significantly higher in the low and high dose groups during the first week of treatment, however the values were essentially identical to the rate of pre-implantation loss observed in controls during the second week and therefore appeared unrelated to treatment. Similarly, resorption rates among these same treatment groups were significantly higher than control, but values from the second week of mating were similar to controls. Further details are presented in Attachment 5.6a.

Litter sizes, number of corpora lutea and number of implantations in the positive control group were significantly lower than control values, with a 2-fold increase in pre-implantation loss during the second week of breeding, and a 10-fold increase in resorption rates during both phases of mating.

5.7 CARCINOGENICITY

Species	: rat
Sex	: male/female
Strain	: Fischer 344
Route of admin.	: gavage
Exposure period	: 103 wk
Frequency of treatm.	: 5 d/wk
Post exposure period	:
Doses	: males 0, 62 or 125 mg/kg bwt/d; females 0, 125 or 250 mg/kg bwt/d
Result	:
Control group	: yes, concurrent vehicle
Method	: other: standard NTP gavage study
Year	: 1986
GLP	: yes
Test substance	: as prescribed by 1.1 - 1.4
Method	: Animals and treatments Male and female F344/N rats (4-6 wk old) were purchased from a commercial supplier, quarantined for 3 wk then randomly assigned to one control and two treatment groups (n = 50/sex/group). Males were treated with 0 (corn oil), 62 or 125 mg PDC/kg bwt/d, 5 d/wk for 103 wk by gavage. Females received 0, 125 or 250 mg/kg bwt/d over the same period. The dosing volume was 3 ml/kg bwt/d (hence stock dosing solution concentrations were 21 mg/ml, 42 mg/ml and 83 mg/ml for the 62, 125 and 250 mg/kg bwt treatments). Dosing solutions were

stored at 0-5 degrees C in dark glass bottles for up to 10 days.

Test sample, stability and achieved concentration
Reagent grade PDC was used, with a purity of 99.4% (GC analysis). Toluene (0.24%) was identified as an impurity (GC/MS). GC-FID analysis demonstrated that 5.7% PDC in corn oil was stable at 25 degrees C for 7 days (recovery = 100% +/- 4%). Duplicate aliquots of the dosing solutions were analysed by GC-FID on 15 occasions during the study. Overall mean recoveries were 95%, 99% and 100% for the 21, 42 and 83 mg/ml solutions, respectively.

Observations

All animals were observed twice daily for signs of morbidity or mortality. Body weights were recorded weekly for the first 13 wk, then monthly thereafter. Moribund animals and all animals that survived to the end of the study were killed and necropsied. Thirty-one major tissues were examined, sampled and processed for histopathological examination.

Histopathological findings

Tissue slides, animal data and summary records were sent to a quality assurance laboratory for independent verification of the diagnoses of the study pathologist. All tumor diagnoses, target tissues and tissues from a randomly-selected 10% of the animals were subject to this assessment. Slides from all target tissues, plus those where the study pathologist and independent pathologist disagreed, were sent for further independent evaluation by a panel of NTP pathologists. The reported findings therefore represent a consensus from these various experts.

Statistical methods

Survival probabilities were estimated using Kaplan-Meier plots, and any treatment-related effect on survival analysed using the method of Cox. Analysis of tumor incidence data used Mantel and Haenszel contingency tables, and included pair-wise comparisons of low or high dose data versus control incidence plus an analysis of overall dose-response trends. Two methods were applied to animals dying before the end of the study. The first (life table analysis) assumed that all tumors of a given type were 'fatal' ie that they directly or indirectly were responsible for the death of the animal. Using this approach the proportion of tumor-bearing animals in the test and control groups were compared every time an animal died of a tumor of interest. The second method (incidental analysis) assume that all tumors observed before 103 wk were 'incidental', and the proportion of animals with tumors compared at 0-52 wk, 53-78 wk, 79-92 wk, wk 93-wk before terminal kill and the terminal kill. The Fisher exact test for pairwise comparisons and the Cochran-Armitage linear trend test for dose-response effects were applied to the tumor data.

Remark

- : Based on tumor findings, NTP concluded that there was no evidence for the carcinogenicity of PDC in male rats, while in females treated with 250 mg/kg bwt/d for 103 wk NTP concluded there was equivocal evidence of an effect based upon a marginal increase in the incidence of mammary adenocarcinomas concurrent with decreased survival and

Result

reduced body weight gain.

A historical incidence of 2% (3/150) was reported for the laboratory conducting this study, with an overall historical incidence of 1.2% (11/895)

Reduced survival and reduced body weight could indicate that treatments exceeded the Maximum Tolerated Dose in female rats.

: Body weight and clinical signs

Treated animals showed a dose-related reduction in body weight. Final body weights were approx. 5% lower than control for low dose animals, and 14% and 24% lower than control in the high dose male and female groups, respectively. (Female body weight was decreased by >20% from wk 76 of the study.) No clinical signs are described.

Survival

The survival of high dose females (250 mg/kg bwt/d) was significantly ($P < 0.001$) below that of the low dose females and controls (32%, 86% and 74% survival to the end of the study). Mortality and morbidity were especially marked at wk 94 of the study. Survival in males was comparable for all groups (78%, 84% and 82% alive at wk 103 for the control, 62 mg/kg bwt/d and 125 mg/kg bwt/d groups, respectively).

Tumor pathology

Because of reduced survival in high dose female rats, statistical procedures that adjust for intercurrent mortality (life table and incidental tumor tests) were regarded as more meaningful than the 'unadjusted' analysis.

A quantitative increased tumor incidence in one or both treatment groups relative to control, or a positive trend in the absence of any statistically significant difference between the treated and control groups, was seen for the following tissues and tumor types:

* mammary gland

mammary gland hyperplasia was increased, and there was a positive trend for mammary adenocarcinoma (adjusted rates: 2.7%, 4.7%, 26.7%; significantly increased in high dose group), both in females only; the overall incidence of fibroadenomas showed a negative trend in females. Tumor incidence in the high dose group was strongly influenced by findings in 4 of 16 animals that survived to the end of the study. A historical incidence of 2% (3/150) was reported for the laboratory conducting this study, with an overall historical incidence of 1.2% (11/895).

* uterus

endometrial stromal polyps occurred with a significant positive trend, although the incidence in the individual treatment groups was not increased relative to control.

* thyroid

follicular cell carcinoma were found in two low dose females (but not in control or high dose females) at study termination; historic range 0.2-0.7%.

* stomach or forestomach

a non-significant increase in squamous cell papillomas was

found in two high dose females (none in control); historic range 0-0.3%.

* pancreas

islet cell carcinomas occurred with a positive trend in males, however the incidence of adenomas was greatest in the control group and the combined incidence (adenoma + carcinomas) was not different between the groups.

* pituitary

while the incidence of adenomas was significantly increased in low dose females, the survival-adjusted incidence was unremarkable; the incidence of pituitary carcinomas was greatest in control females; the incidence of combined (adenomas + carcinomas) was not increased significantly.

* adrenal glands

pheochromocytomas showed a negative trend in males, and there was no difference in the incidence in combined pheochromocytoma + malignant pheochromocytoma).

No tumors were present in liver, a tissue showing signs of non-neoplastic changes (see above).

Note: Significant increases were observed in virus antibody titers. The report notes that the relationship between these increases and occurrence of non-neoplastic- and neoplastic changes is unclear.

**Source
Conclusion**

- : The 1,2-Dichloropropane ICCA/HPV Consortium
- : NTP concluded that under the conditions of this study there was no evidence that PDC was a carcinogen in male rats treated by gavage at doses up to 125 mg/kg bwt/d or 250 mg/kg bwt/d, respectively, for up to 103 wk. There was equivocal evidence of an increase in mammary tumors in high dose females, but no other tissues were affected.

The second method (incidental analysis) assume that all tumors observed before 103 wk were 'incidental', and the proportion of animals with tumors compared at 0-52 wk, 53-78 wk, 79-92 wk, wk 93-wk before terminal kill and the terminal kill. The Fisher exact test for pairwise comparisons and the Cochran-Armitage linear trend test for dose-response effects were applied to the tumor data.

Remark

- : The liver was the principal target for PDC toxicity in the mouse, with hepatocytomegaly and hepatic focal necrosis seen in male mice only. It was also the key site for tumor formation.

Hepatocellular adenoma is a common finding in control B6C3F1 mice. Historic control data for this lesion in NTP studies conducted to 1995 (corn oil gavage, 16 studies) returned an incidence of 267/813 or 33% in males, with a range of 14-58%; equivalent values for females were 111/809 = 14%, with a range of 2-28% (Source: Analytical Services Inc. (1995) Tumor Incidence in Control Animals by Route and Vehicle of Administration: B6C3F1 Mice. prepared for NIEHS, 6 June 1995).

Comparison of this historic control information with findings from the NTP leads to the following conclusions:

- * The control incidence of hepatocellular adenoma for male (20%) and female (3%) mice from this NTP study was markedly lower than the mean historic incidence (33% in males; 14% in females);
- * The incidence of hepatocellular adenoma in high dose males (45%) was within the spontaneous range (14-58%);
- * The incidence of hepatocellular adenoma in low- (17%) and high dose (19%) female mice was also within the spontaneous range (2-28%);
- * Liver tumor incidence in both sexes appeared non-linear when related to received dose.

Result**: Body weight and clinical signs**

Mean body weights of treated and vehicle control animals were comparable, and no compound-related clinical signs were noted.

Survival

The survival of high dose females (250 mg/kg bwt/d) was significantly ($P < 0.035$) less than that of the low dose females and controls, with 70%, 58% and 52% of the control, low and high dose animals surviving to termination. Survival in males was comparable for all groups (70%, 66% and 70% alive at wk 103 for the control, 125 mg/kg bwt/d and 250 mg/kg bwt/d groups, respectively). The report notes that the lowered survival in female mice was related to an increased incidence of reproductive tract infections in animals which died before the end of the study (45% of controls affected versus 64% of both the low and high dose females that died during the study).

Non-tumor pathology

Hepatocytomegaly (6%, 10% and 30% for control, low dose and high dose animals, respectively) and hepatic focal necrosis (4%, 10% and 20%) were seen in male mice only. Acanthosis of the surface epithelium of the forestomach occurred at increased incidence in high dose males (0%, 0%, 4%) and both groups of treated females (0%, 10%, 8%). Suppurative inflammation (affecting ovary, uterus or multiple organs) was found in 5/11 control, 9/14 low dose and 14/22 high dose females that died before the end of the study.

Tumor pathology

Tumors were found in the following tissues, although the increase was not always statistically significant and/or dose-related:

*** liver**

There was a positive trend for liver adenomas in male (20%, 29%, 45%, adjusted for intercurrent mortality) and female (3%, 17%, 19%, adjusted) mice. Tumor incidences in high dose

males ($P=0.017$, lifetable test) and both low (0.064, lifetable test) and high dose ($P=0.047$, lifetable test) females were increased significantly relative to control.

* thyroid

Two high dose females had follicular cell carcinomas, and 3 had follicular cell adenomas. The combined incidence of adenomas or carcinomas in high dose females (21% adjusted) was increased significantly ($P=0.040$, lifetable test) relative to the controls (3% adjusted), with a historical rate of 1%-3.8%. There were no tumors in the controls.

* forestomach

Squamous cell papillomas occurred at an incidence of 0%, 2% and 6% in control, low dose and high dose male mice, and at 0%, 4% and 4% in the equivalent female groups. Historical rates for this tumor are in the range 0-0.2% for male B6C3F1 mice and 0-0.3% for females. One high dose female had a squamous cell papilloma (2% incidence, historical range of 0-0.3%).

* lung

Alveolar/bronchiolar adenomas and alveolar/bronchiolar adenomas or carcinomas (combined) showed a significant negative trend in female mice.

* external surface

Subcutaneous fibromas or fibrosarcomas and fibromas or fibrosarcomas of the skin or subcutaneous tissue occurred with a significant negative trend in male mice.

Note: Significant increases were observed in virus antibody titers. The reports notes that the relationship between these increases and occurrence of the non-neoplastic and neoplastic changes is unclear.

Source	:	The 1,2-Dichloropropane ICCA/HPV Consortium
Conclusion	:	NTP concluded that under the conditions of this study PDC increased the incidence of hepatic adenomas in B6C3F1 mice treated with 125 mg/kd bwt/d or 250 mg/kg bwt/d by gavage for up to 103 wk.
Reliability	:	(1) valid without restriction Comparable to guideline study, with restrictions.

5.8.1 TOXICITY TO FERTILITY

Type	:	Two generation study
Species	:	rat
Sex	:	male/female
Strain	:	Sprague-Dawley
Route of admin.	:	drinking water
Exposure period	:	41 wk (f0 adults)
Frequency of treatm.	:	daily
Premating exposure period		
Male	:	10 - 14 wk
Female	:	10 - 14 wk
Duration of test	:	

No. of generation studies : 2
Doses : 0.024%, 0.10%, 0.24%
Control group : yes, concurrent vehicle
NOAEL parental : = .024 %
NOAEL F1 offspring : = .1 %
NOAEL F2 offspring : = .1 %
other: reproduction : = .24 %
NOEL
Method : EPA OTS 798.4700
Year : 1990
GLP : yes
Test substance : as prescribed by 1.1 - 1.4

Method : Animals and treatments
Male and female SD rats were purchased at 4 wk of age from a commercial supplier, stratified by weight and randomly assigned to treatment groups upon receipt. After two weeks acclimatization, PDC was administered in drinking water at concentrations of 0 (control), 0.024%, 0.10% or 0.24% (w/v).

Preparation of dosing solutions

The high dose exposure concentration was selected based upon the theoretical maximal solubility of PDC in water (ie 0.27 g/100 ml). Stability testing showed that >90% of the initial concentration of high dose solution was recovered after 21 days, therefore fresh solutions were prepared at weekly intervals. The lower exposure concentrations were prepared by dilution of the 0.24% solution. All dosing solutions were administered to the animals using sealed Tedlar gas and water sampling bags, fitted with a pressure-activated stainless steel nipple, in order to minimise losses by volatilization. All dosing solutions were analysed on at least 3 occasions per generation during the study. (Note: the analytical method used is not stated, however a limit of detection of 3.08 - 10.1 ug/ml is reported.)

Experimental design

The f0 generation comprised 30 male and 30 female rats per group, and treatment commenced at 6 wk of age. After approx. 10 wk treatment, f0 animals were mated (one male to one female) to produce the f1 litters. Following weaning (3 wk old), 30 males and 30 females from the f1 litters were randomly selected to be the parents of the next generation. Following approx. 12 wk treatment, the f1 adults were mated to produce the f2 litters. For the f1 mating, cohabitation of male and female littermates was avoided.

To reduce variation in pup growth, f1 and f2 litters with greater than 8 pups were reduced in size on PND 4 to 4 males and 4 female. Litters with 8 or fewer pups were not culled. Weaning of all litters occurred 3 weeks after delivery.

Further details of the experimental design are given in Attachment 5.8.1a.

Parental observations

Body weight and food and water consumption were recorded weekly in males and in females pre-parturition, and at 3 day intervals in females post-parturition. f0 and f1 adults were subject to a complete necropsy after the last litter from

each generation had been weaned. Liver, kidney and a representative range of other tissues were weighed, sampled and preserved. Bone marrow, coagulating glands, epididymides, kidneys, ovaries, oviducts, pituitary, prostate, seminal vesicles, testes, uterus, vagina and any abnormal gross lesions from the control and high dose groups (f0 and f1) were processed and examined by light microscopy.

Hematology parameters (hematocrit, hemoglobin concentration, red cell count, total white cell count, platelet count, red cell morphology) were determined in f0 and f1 animals using blood collected from 10 rats/sex/dose level at necropsy.

Litter observations

All litters were examined as soon as possible after delivery, and parturition date, litter size, weight and sex of each pup and number of live and dead pups on PND 0-21 recorded. Any physical abnormalities at birth or during lactation were recorded.

Weanling observations

10 pups/sex/dose level from the f0 and f1 generations were randomly selected for necropsy at weaning. Liver and kidney weights were recorded, and hematology parameters determined (same details as adults). Tissues were sampled and preserved, but not subject to histopathological assessment.

Statistics

Body weights, organ weights, litter size, hematology and gestation data were evaluated by Bartlett's test for equality of variances, followed by either parametric or non-parametric ANOVA. If the ANOVA was significant, a Dunnett's test or the Wilcoxon Rank-Sum test with Bonferroni's correction was performed. Descriptive statistics were reported for food and water consumption. Fertility indices were evaluated by the Fisher exact probability test and neonatal sex ratios analysed by the binomial distribution test. Survival indices and other neonatal incidence data were analyzed using the litter as the experimental unit.

Result

- : Analysis of dosing solutions and received dose
Mean exposure concentrations (determined on 3-4 occasions and presented as percent nominal with SD in parentheses) for the low, mid and high dose groups were as follows:
f0 males: 88.8 (6.1), 98.2 (7.3), 100.0 (8.2)
f0 females: 90.3 (6.9), 100.4 (4.3), 102.4 (8.4)
f1 males: 100.7 (29.0), 96.0 (0.9), 95.3 (2.2)
f1 females: 94.6 (21.8), 97.7 (2.6), 96.1 (3.1)

GENERAL

See Attachment 5.8.1 summary.doc for an overview of the main findings from this study.

PARENTAL GENERATIONS

Received dose

Based upon mean body weight and water consumption data, males of both generations from the low, mid and high dose groups received approx. 20 - 30, 70 - 130 and 130 - 250 mg/kg bwt/d. Equivalent female groups received 30 - 40, 110 - 140 and 190 - 270 mg/kg bwt/d. Female water consumption increased during lactation, with received doses of approx 60, 200 450-500 mg/kg bwt/d. Further details are presented

in Attachment 5.8.1b.

In life observations

No treatment-related clinical signs were observed.

Food consumption

There were relatively minor and sporadic effects on food intake. f0 females from the high and low dose groups consumed 10% and 6% less than the controls, while f1 males from the high dose group showed an overall 8% reduction in food consumption (pre-mating and mating phases). Food intake data for the other groups were generally unremarkable.

Water consumption

A dose-related decrease in water consumption was apparent in animals from both the f0 and f1 generations, presumably reflecting reduced palatability in the mid and high dose groups. Overall, water consumption in high dose males and pregnant females was 50-60% of control, and 70% of control in lactating females. Water intake in mid dose males and mid dose pregnant females was 70 - 80% of control, and 75 - 85% of control consumption in mid dose lactating females. Results for the low dose animals were 90 - 104% of control.

NOTE: Water consumption typically increases from around gestation day 13 in order to compensate for increased plasma and extracellular fluid volumes during the late stages of pregnancy. This was not the case in this study, due to the unacceptable palatability of the drinking water. This would be expected to have an adverse influence on fetal development. It is also pertinent that water consumption in untreated (control) females increased in this study during lactation, whereas major reductions were apparent in treated animals during lactation. This would be expected to have impacted post-natal survival of the pups.

Parental body weight

Body weights for the high dose animals were significantly ($\alpha = 0.05$) lower than control in f0 and f1 generations of both sexes. In terms of affecting reproductive outcomes, effects in females appeared particularly important. Thus body weights for high dose f0 and f1 females were 5% and 11% lower than control during the pre-mating period, with a 10 - 12% decrement present during gestation and an approx. 15% reduction during lactation. Gestation body weight gains were decreased by approx. 20% in f0 and f1 females given 0.24% PDC, and by 7-13% in females given 0.1% PDC. Less consistent body weight decrements were noted in the mid dose animals, with negligible effects in the low dose generations.

Reproductive indices

There were no significant or obvious treatment-related differences in male or female reproductive performance, as assessed from mating- and conception indices, fertility or gestational period. Sporadic differences seen for some female parameters were not dose-related (ie present in low and/or mid but not high dose animals) or were within the range of historic control data. All females produced viable litters.

Hematology

Sporadic hematological changes noted in this study were not

dose related and inconsistently expressed in males and females of the same generation and in same sex animals of different generations. Overall these effects appeared incidental and unrelated to treatment with PDC.

Necropsy observations

Increased relative kidney weight values in high dose animals (both sexes) appeared secondary to a lower terminal body weight. No gross pathological changes were noted in any of the parental animals.

Histology

Treatment-related histologic changes were limited to increased hepatocellular granularity (adaptive change) in males and females of both generations at all dose levels. Although no statistical analyses are reported, the incidence in high dose females (17% and 10% for f0 and f1, respectively) and high dose f1 males (13%) appears greater than control (0 - 2% for all sex/generation groups). The response in f1 high dose males (5% incidence) and mid and low dose animals of the other generations were less pronounced (2 - 8% incidence) and/or not dose related. All other tissues, including reproductive organs from both sexes, were unremarkable.

LITTER DATA

There were no significant treatment-related external observations or difference in sex ratio in either generation. The number of pups born alive was similar in the control and test groups from both phases of the study, however postnatal survival in high dose f1 litters was significantly lower than control while that of the high dose f2 litters was 10% lower than controls on PND 14 and 21; these effects appeared treatment-related. Bodyweights for high dose f0 neonates were significantly decreased, with day 21 values approx. 15% lower than control. Bodyweights of f1 litters were less severely affected (4 - 7% reduction), and attained significance only on lactation day 21.

WEANLING DATA

An increased hemoglobin concentration in high dose f1 males and an increased mean relative kidney weight in high dose f1 females appeared related to a lowered water intake and body weight, respectively. All other hematological and gross necropsy observations were comparable to control in both the f1 and the f2 generations.

- Attachment 5.8.1a.doc
- Attachment 5.8.1b.doc

Conclusion

- : Propylene dichloride was not a reproductive toxin when tested over 2 generations in SD rats exposed to 0.024%, 0.1% and 0.24% in drinking water.

Decreased water consumption (presumably reflecting unacceptable palatability of the test solution) and lowered body weight, and increased hepatocellular granularity (adaptive change), were present in parental animals from the 0.24% groups of both generations. Neonatal growth and survival were decreased in the 0.24% treatment groups, probably in response to decreased maternal water intake and lower

5. Toxicity

Id 78-87-5

Date 14.12.2004

	growth. There was no effect on reproductive performance, live births or litter size in any of the test groups.	
	Thus the NOAEL for adults and neonatal effects was 0.1% PDC while the reproductive NOEL was 0.24% PDC, the limit of solubility.	
Reliability	: (1) valid without restriction	
Flag	: GLP guideline study.	
25.10.2004	: Critical study for SIDS endpoint	(213)
Type	: Two generation study	
Species	: rat	
Sex	: male/female	
Strain	: Sprague-Dawley	
Route of admin.	: drinking water	
Exposure period	: F0 males 20 weeks, F0 females 20 weeks F1 males 21 weeks, F1 females 21 weeks	
Frequency of treatm.	: daily	
Premating exposure period		
Male	: F0 10 weeks, F1 12 weeks	
Female	: F0 10 weeks, F1 12 weeks	
Duration of test	: 41 weeks	
No. of generation studies	:	
Doses	: 0.024, 0.10 and 0.24 % in drinking water	
Control group	: yes, concurrent no treatment	
NOAEL parental	: = .024 %	
NOAEL F1 offspring	: = .1 %	
Method	: other: Two-generation Reproduction Toxicity Test	
Year	: 1988	
GLP	: yes	
Test substance	: as prescribed by 1.1 - 1.4	
Remark	: The F0-animals were exposed to 1,2-dichloropropane in drinking water first for a period of 10 weeks before mating, then for a maximum 3 weeks during mating and finally during feeding of the young. The animals of the F1-generation were analogously treated. F2 animals were dosed until they were 21 days old; 30 animals/sex/dosage and control group.	
Result	: No influence (substance-related) on reproduction parameters (fertility and brood parameters) was observed. The survival rate and the average body weight gain of the F1 -young animals were significantly ($p \leq 0.05$) decreased in the 0.24% dosage group from postnatal day 1 - 21 (10 % mortality, difference in body weight approximately 15 % compared to the control group). These changes were not considered as a direct toxic effect of 1,2-dichloropropane, but as a secondary effect of the reduced maternal drinking water consumption. No other substance-related changes were found in the analyzed organs of F0- and F1-animals (liver in all concentration groups; other reproductive organs, kidney, hypophysis and marrow in the high dosage group) other than the increase in hepatocellular granulation for all dose groups.

5.8.2 DEVELOPMENTAL TOXICITY/TERATOGENICITY

Species	: rat
Sex	: female
Strain	: Sprague-Dawley
Route of admin.	: gavage
Exposure period	: GD 6 - 15 inclusive
Frequency of treatm.	: daily
Duration of test	:
Doses	: 0 (corn oil), 10, 30 or 125 mg/kg bwt/d
Control group	: yes, concurrent vehicle
NOAEL maternal tox.	: = 30 mg/kg bw
NOAEL teratogen.	: = 125 mg/kg bw
NOAEL Fetotoxicity	: = 30 mg/kg bw
Method	: EPA OTS 798.4900
Year	: 1995
GLP	: yes
Test substance	: as prescribed by 1.1 - 1.4

Method : Animals and treatments
Pregnant female SD rats (approx. 14 wk old, n = 30) were randomised into groups and administered PDC by gavage at doses of 0 (corn oil), 10, 30 or 125 mg/kg bwt/d on GD 6-15 inclusive.

The concentration of PDC in the dosing solutions was verified using GC-FID.

Parental observations

Animals were observed daily in their cages, and also subject to a more intensive clinical examination 30 - 60 min post-dosing. This included observation of pupil size, respiration, movement (muscle tone, extensor thrust reflex, general behaviour, tremors, convulsions etc), condition of skin and haircoat (ie piloerection), salivation, lacrimation and any other abnormal events. Food and water intake was recorded every 2 - 4 days, and body weights on GD 0, 16 and 21. The dams were sacrificed on GD 21, when liver, kidney, spleen and gravid uterine weights were recorded.

Fetal observations

The number of corpora lutea, the number and position of implantations and the number of live or dead fetuses were recorded. In addition, the sex and body weight of each fetus was recorded, and any gross external alterations recorded. At least one-half of each litter was examined immediately for visceral alterations, with subsequent evaluation of skeletal abnormalities using alizarin red-S.

Statistics

The data were analysed initially using Bartlett's test, parametric or non-parametric ANOVA, Dunnett's test and the Wilcoxon Rank-Sum test. Pregnancy rates were analysed using the Fischer exact probability test, and fetal sex ratios evaluated using a binomial distribution test.

Interpretation of findings

Final interpretation of the results considered statistical analyses along with other factors such as historical data, dose-response relationships and whether the findings were biologically significant in the light of other toxicological

Result

and pathological findings. This is scientifically acceptable since a high level of Type I (false positive) errors would be anticipated as a consequence of the large number of statistical comparisons that were included in the study.

: Mean analysed concentrations of PDC were 5.0 (0.0), 15.0 (0.0) and 62.5 (2.0) mg/ml (SD in brackets).

Maternal observations

Clinical signs (ie decreased movement and muscle tone, increased lacrimation, decreased extensor reflex and increased salivation) were present in high dose animals on GD 6 and to a lesser extent on GD 7. Despite the transitory nature of these changes, they appeared indicative of an adverse effect in dams from the high dose group. No clinical effects were seen on other days in the high dose group, or on any day in the mid- or low dose animals.

Body weights were slightly (3-5%) but significantly lower in high dose dams throughout the study. Body weight gain was decreased significantly in high dose dams on GD 6-9, and although comparable to control during the mid- and latter stages of pregnancy the overall weight increase in the 125 mg/kg bwt/day group was approx. 30% lower than controls on GD 6-16 (that is, during the dosing period). Food consumption was reduced approx. 25% on GD 6-9, and water consumption increased by the same amount on GD 9-12 and 12-15.

There were no significant effects on absolute or relative organ weights, or on uterine weights or pregnancy parameters (including number of litters, corpora lutea per dam, implantations per dam, live fetuses per litter, resorptions, fetal bwt, etc).

Fetal observations

A low incidence of malformations was present in all groups, with no qualitative or quantitative increase in litters from treated dams. Overall there was no indication that PDC was a teratogen.

Fetal variations were present in both control and treated groups. The only treatment-related effect was a significant increase in the incidence of delayed ossification of the bones of the skull among fetuses from the high dose group. Interestingly, the occurrence of this observation was most common in high dose litters containing 16 or more pups. All other parameters were comparable to the controls.

Source**Conclusion**

: The 1,2-Dichloropropane ICCA/HPV Consortium
: Under the conditions of the study, mild fetotoxicity (as evidenced by decreased ossification of the bones of the skull) was noted in litters from dams given 125 mg/kg bwt PDC/day. This effect was most common in the larger litters, and was co-incident with significant reductions in body weight gain and food consumption. It is concluded that the NOAEC for both maternal and fetal toxicity was 30 mg/kg bwt/day.

Reliability

: (1) valid without restriction

(215)

Species : rabbit
Sex : female
Strain : New Zealand white
Route of admin. : gavage
Exposure period : GD 7 - 19 inclusive
Frequency of treatm. : daily
Duration of test :
Doses : 0 (corn oil), 15, 50 or 150 mg/kg bwt/ d
Control group : yes, concurrent vehicle
NOAEL maternal tox. : = 50 mg/kg bw
NOAEL teratogen. : = 150 mg/kg bw
NOAEL Fetotoxicity : = 50 mg/kg bw
Method : EPA OTS 798.4900
Year :
GLP : yes
Test substance : as prescribed by 1.1 - 1.4

Method : Animals and treatments
 Artificially-inseminated pregnant female New Zealand rabbits (approx. 6.5 mo old, n = 18) were randomised into groups and administered PDC by gavage at doses of 0 (corn oil), 15, 50 or 150 mg/kg bwt/ d on GD 7 - 19 inclusive.

The concentration of PDC in the dosing solutions was verified using GC-FID.

Parental observations
 Food and water intake was recorded every 2 - 4 days, and body weights on GD 0, 20 and 28. Blood samples were collected on GD 19 and subject to an extensive haematological examination. The dams were sacrificed on GD 28, when liver, kidney, spleen and gravid uterine weights were recorded.

Fetal observations
 The number of corpora lutea, the number and position of implantations and the number of live or dead fetuses were recorded. In addition, the sex and body weight of each fetus was recorded, and any gross external alterations recorded. All rabbit litters were examined immediately for visceral alterations, with subsequent evaluation of skeletal abnormalities using alizarin red-S.

Statistics
 The data were analysed initially using Bartlett's test, parametric or non-parametric ANOVA, Dunnett's test and the Wilcoxon Rank-Sum test. Pregnancy rates were analysed using the Fischer exact probability test, and fetal sex ratios evaluated using a binomial distribution test.

Interpretation of findings
 Final interpretation of the results considered statistical analyses along with other factors such as historical data, dose-response relationships and whether the findings were biologically significant in the light of other toxicological and pathological findings. This appears scientifically acceptable since a high level of Type I (false positive) errors would be anticipated as a consequence of the large number of statistical comparisons that were included in the study.

Result : Mean analysed concentrations of PDC were 14.8 (0.06), 49.4 (0.34) and 150.0 (1.94) mg/ml (SD in brackets).

Maternal observations

One rabbit from the high dose group died on GD 22 (ie after gavage treatment had ended) but no cause of death could be identified at necropsy. The remainder of the high dose dams exhibited intermittent anorexia (data not presented). There were no other significant changes in behaviour or demeanor among rabbits during the course of the study.

Body weight gain among the high dose dams was significantly lower than that of the controls (net loss of 165 g compared to a net gain of 49 g in the controls on GD 7-20), although absolute bwt appeared unaffected.

Haematological examinations demonstrated the clear effects in high dose dams (other groups unaffected), with red cell counts, haemoglobin concentration and haematocrit all decreased by 18-20% while platelet and white cell counts were increased 20-25%. The percentage of reticulocytes was approx. double in high dose animals when compared to the controls.

There were no significant effects on absolute or relative organ weights, or on uterine weights or pregnancy parameters (including number of litters, corpora lutea per dam, implantations per dam, live fetuses per litter, resorptions, fetal bwt, etc).

Fetal observations

There was no increase in the incidence of malformations in any of the treated groups when compared with the controls. Overall there was no indication that PDC was a teratogen.

Fetal variations were present in both control and treated groups. The only treatment-related effect was a significant increase in the incidence of delayed ossification of the bones of the skull among fetuses from the high dose group. All other parameters were comparable to the controls.

Source
Conclusion

- : The 1,2-Dichloropropane ICCA/HPV Consortium
- : Under the conditions of the study PDC was not selectively toxic to the fetus, causing a slight delay in ossification of the fetal skull at doses causing systemic (haematological) changes in the dams. The NOAEL for maternal and fetal effects in the rabbit is 50 mg/kg bwt.

Reliability

- : (1) valid without restriction
- GLP guideline study.

5.8.3 TOXICITY TO REPRODUCTION, OTHER STUDIES

5.9 SPECIFIC INVESTIGATIONS

Endpoint	: Neurotoxicity
Study descr. in chapter	:
Reference	:
Type	:
Species	: rat

Sex	: male/female
Strain	: Fischer 344
Route of admin.	: gavage
No. of animals	: 15
Vehicle	: other: corn oil
Exposure period	: 90 day(s)
Frequency of treatm.	: 5 d/wk for 13 wk
Doses	: 0, 20, 65 or 200 mg/kg bwt
Control group	: yes, concurrent vehicle
Observation period	: 13 wk during treatment + 9 wk recovery period
Result	: No gross or histopathologic changes in central or peripheral nervous system
Method	: other: functional observation battery = EPA 798.6050; motor activity = EPA798.6200; neuropathology = EPA798.6400.
Year	: 1988
GLP	: yes
Test substance	: as prescribed by 1.1 - 1.4

Method : Animals and treatments
Male and female F344 rats (approx. 8 wk old; n=15/sex) were administered 0 (control, corn oil, 1ml/kg bwt), 20, 65 or 200 mg PDC/kg bwt/d via gavage, 5 d/wk for 13 wk (equivalent to a total of 65 treatments). Fresh dosing solutions were prepared monthly, and the concentration of PDC confirmed using GC.

A dose of 200 mg/kg bwt/d was chosen for the high dose group based on the known acute CNS effects of PDC ie this level of exposure was expected to significantly challenge the animals but not cause frank systemic toxicity.

After 13wk treatment, 4 rats/sex/dose were randomly selected for terminal examinations. The remainder were allowed a 9 wk recovery period, after all were sacrificed and 5 rats/sex/dose were taken for necropsy.

Cage side observations were conducted twice daily. The animals were also subject to handling and observation at the time of dosing, and subjected to a detailed external examination each week.

Functional Observational Battery (FOB)
The animals were subjected to FOB evaluation before treatment commenced and at monthly intervals during the main study period. The observations were conducted by the same technician before the daily dosing. Endpoints included:

- *Observations in-hand
 - pupil size
 - respiration
 - movement
 - condition of skin and coat
 - salivation
 - lacrimation
 - urine staining
 - faecal staining
- * Observations in a clear plastic box
 - locomotor behaviour
 - responsiveness to touch
 - responsiveness to sharp noise
 - responsiveness to tail pinch
 - visual placing

Grip strength

Hindlimb grip strength was measured before treatment commenced and at monthly intervals during the main study period. The test involved placing the rat's forelegs on a bench and the hindfeet on a horizontal screen attached to a strain gauge. The observer then smoothly but firmly pulled backward on the tail until the grip of the hind feet was broken. The strongest response from three trials was used for statistical analysis.

Motor activity

Motor activity was evaluated before treatment commenced and at monthly intervals thereafter in a doughnut-shaped plexiglass alley over five 8 min sessions. An infrared photo beam crossed the alley in two locations to record movement.

Body weight and temperature

Body weights were recorded weekly and also on the days when the FOB and motor activity assessments were conducted. Body temperature was recorded using a thermistor on the last day of dosing concurrently with the FOB.

Necropsy

Four rats/sex/dose level were fasted overnight prior to necropsy. The animals were given heparin prior to anesthesia, then sacrificed by whole body perfusion and fixing with gluteraldehyde/formaldehyde solution. A macroscopic examination (limited in extent by the perfusion process) was performed prior to removal of the brain and selected nervous system tissues. The liver, kidneys and spleen (possible target tissues) were sampled and preserved.

Histopathology

The following nervous system tissues from control and high dose animals were subject to the microscopic evaluation:

- brain (6 levels)
- spinal cord (cervical and lumbar)
- Gasserian ganglia
- dorsal and ventral spinal nerve roots
- dorsal root ganglia (cervical and lumbar)
- sciatic, tibial and sural nerves

Special stains were used to examine neuronal bodies, axons and neurofibrils and myelin.

Recovery phase

11 rats/sex/dose level were retained for possible further examination, pending preliminary assessment of findings from the main study. The animals were observed for clinical signs twice daily and subject to a more detailed external examination each week. Body weights were recorded weekly, and body temperature recorded 1, 2, 4 and 8 wk after treatment ended. Five rats/sex/dose were taken for necropsy after a 9 wk recovery period, the remainder were euthanized without further examination.

Statistical analysis

The data were subject to extensive statistical evaluation, including Bartlett's test, parametric and non-parametric ANOVA, Dunnett's test, Wilcoxon Rank-Sum test, Bonferroni correction, Outlier test, 2-way ANOVA. In view of the very large number of comparisons considered in this study, the final interpretation of the data considered results from

Result

statistical analyses along with other factors such as dose-response relationships and whether the results were meaningful in the light of other findings.

: Dosing solutions

Analysis of the dosing solutions demonstrated that the concentration of PDC was at or slightly above the target, varying from 100 to 110.5% of nominal. There was no appreciable loss due to volatilisation (<6% decrease) and the PDC was distributed in a homogeneous manner within the master batch of each solution.

General

All rats survived the 13 wk treatment period. Clinical signs included lacrimation and blinking in a dose-dependent manner on the first day, with decreased spontaneous motor activity (for up to 4 hr post-treatment in the high dose group). No effect on motor activity was noticeable in the low- and mid dose groups by day 3, or in the high dose animals by day 4. No other treatment-related clinical signs were present.

Body weight

A significant decrease in body weight of high dose males was apparent during the first week of treatment which persisted throughout the 13 wk dosing period (6-10% reduction overall). Body weights of mid dose males were also decreased consistently and, although the change was not always significant, this was also considered to be treatment related by the authors of the study report. Body weights of high dose females were also slightly decreased (equivocal, non-significant effect). There was no effect on the body weights of low dose males or mid and low dose females.

FOB

No differences were apparent between control and treated animals at any of the test intervals.

Hind limb grip strength

The only statistically significant effect noted was an increase in grip strength in high dose animals (both sexes) 1 month following the start of treatment. This finding was not replicated 2 or 3 months into the study, and was considered coincidental to treatment.

Motor activity

Data generated during the study did not reveal any significant differences between control and treated animals. Females tended to be more active than males at the 1- and 3 month evaluation points, however there was no [sex x treatment] interaction and this finding was considered incidental.

Body temperature

There was a slight but significant decrease in body temperature in high dose animals at the end of the main phase of the study (0.6 degree C reduction in females, 0.3 degree C reduction in males).

Observations at necropsy

There were no gross changes observed at necropsy that were considered related to treatment with PDC. Absolute brain weight was decreased by approx. 10% in high dose animals, probably reflecting the lower body weight noted above.

Relative brain weight was marginally increased.

Histopathologic observations

A few incidental observations were identified however the incidence was similar in control and high dose animals, and the changes were considered unrelated to PDC treatment.

Recovery phase

Body weight decreases present in high dose males at the end of the main phase of the study were maintained throughout the 9 wk recovery phase (significant 8% decrease in high dose males at wk 22). Mid dose males and high dose females showed a non-significant 3-4% reduction in bwt over the same period.

Body temperature differences in high dose animals generally remained during the recovery period (significantly decreased by 0.6 - 1.0 degree C in females throughout recovery phase, 0.3-0.5 degree C reduction in males during wk 1-4 only).

Source Conclusion

- No gross lesions were identified at necropsy.
- : The 1,2-Dichloropropane ICCA/HPV Consortium
- : Under the conditions of the study, early transient clinical signs and minor decreases in body weight and body temperature were the only effects attributable to PDC. A NOAEL of 20 mg/kg bwt/d was established in males (reflecting bwt effects only) and a NOAEL of 65 mg/kg bwt in females. The NOAEL for gross, microscopic and functional effects on the central and peripheral nervous system was 200 mg/kg (the highest doses tested) bwt in both sexes.

Reliability

- : (1) valid without restriction
- GLP guideline study.

5.10 EXPOSURE EXPERIENCE

Type of experience

- : Human

Remark

- : An unconscious 71-year-old man was taken to the hospital approximately 1 hour after attempting suicide by ingesting approximately 180 ml of a cleaning agent (labelled as 90 % 1,2-dichloropropane and 10 % 1,1,1-trichloroethane). He died after 48 hours never regaining consciousness. Upon arrival his liver and renal functions as well as coagulation were normal but 8 hours later, severe liver dysfunctions appeared. These dysfunctions were detected by a strong increase of transaminase activity in serum. After 48 hours aspartate aminotransferase activity was 5,912 U/l (upper normal value 19U/l), the alanine aminotransferase was 30,128 U/l (normal value 5-23 U/l) and prothrombin activity was lower than 10%. Further, the following were measured: a bilirubin content of 2.3 mg/100 ml (normal value < 1mg/100ml), a creatinine content of 2.8mg/100ml (normal value 0.7 -1.1 mg/100 ml), an increased activity of cholinesterase up to 2100 U/l, a fibrinogen content of 96 mg/100 ml (normal value 150-450 mg/100 ml) and 14000 blood platelets/ul. During the hospital stay, the patient was diagnosed with severe liver and renal dysfunction, abnormal coagulation (coagulopathy), metabolic acidosis, myocardial

	insufficiency and shock.	
	Estimated dose (180mL of 90% PDC) is 3400 mg/kg/day for a 60kg 71-year old.

20.10.2004		(217) (218)
Type of experience	: Human	
Remark	: A 20-year-old girl was taken to a hospital with vomiting and abdominal pains. During the examination oliguria, epistaxis, hematuria, metrorrhagia as well as periorbital and conjunctival hemorrhages were found. The clinicochemical examination showed acute liver disease (increased activities of alanine and aspartate aminotransferase as well as an increased bilirubinemia and a decreased prothrombin level), severe kidney disease (hypercreatininemia and decreased urea value), hemolytic anemia and intravascular coagulation (increased fibrinolytic split products; number of thrombocytes 10,000/mm ³). Further, complement factors C3 and C4 were not detectable. Three weeks after a blood transfusion and a hemofiltration, the liver, kidney and coagulation dysfunction were no longer detectable. Review of the patient's medical history presumed a connection between appearance of these symptoms and the abuse of "Trielina". The patient was sniffing "Trielina" for approximately 1 month, stopped for 10 months and then started again - the above-mentioned intoxication symptoms returned. The product contained 98% 1,2-dichloropropane and 2% trichloroethylene and dichloroethane based on GC analysis.

Type of experience	: Human	
Remark	: A unconscious 49-year-old man was taken to the hospital after attempting suicide by ingesting an unknown amount of 1,2-dichloropropane, as identified by GC/MS. The patient was given artificial respiration and regained consciousness 3 days later. He was diagnosed with esophagitis. The following biochemical parameters were analyzed in serum at different times: alanine aminotransferase activity and the bilirubin content were increased for the first 2 weeks but normalized within approximately 1 month; Three days after arrival the prothrombin content severely decreased (20% of the starting value) and 9 days later it returned to normal. One month after intoxication, hepatomegaly and splenic enlargement as well as ascites appeared. Liver biopsy revealed hepatocellular necrosis accompanied by an inflammatory reaction. Six months later another biopsy was taken; portal hypertension and portal fibrosis were found but there was no remaining evidence of hepatocyte necrosis.

Type of experience	: Human	
Remark	: A 46-year old man fell in a deep coma with pupil dilation and hypertension within 2 hours after ingesting approximately 50 ml of a cleaning agent by mistake; the man gained consciousness 24 hours after being given artificial respiration and osmotic diuresis. A little bit later delirium and tremor appeared. The man died 36 hours after intake, of irreversible shock with heart failure, acidosis and hepatic cytolysis. Autopsy showed a centrilobular and mediolobular acute necrosis of the liver. Gas chromatography analysis of the cleaning agent demonstrated qualitatively the presence of 1,2-dichloropropane .

20.10.2004		(221)
Type of experience	: Human	
Remark	: In a letter to the editor, a case report is described for a 73 yr old woman who was admitted to hospital with vomiting and somnolence. Three days earlier she had developed abdominal pains. The patient had been cleaning garments using a stain remover containing 1,2-dichloropropane (no analytical confirmation of composition). She reported having fallen asleep for 2 hr with her head about 40 cm away from the open glass of cleaning fluid. Laboratory tests revealed decreased serum potassium, hyperglycemia and leukocytosis. Serum ASAT increased from 2114 U/l on the day of admission to 6300 U/l the following day, and serum ALAT from 1990 U/l to 5400 U/l; prothrombin activity decreased from 31% of normal to 22% of normal over the same period. Her condition had improved by day 5 (no details). Hepatic biopsy on day 8 revealed centrilobular necrosis, characterised by pyknosis and 'cellular shadows'. Haemolytic anaemia (Hb 9.8 g/l; 3.01×10^6 ul red cells; HCT 30%) was present at day 10 and persisted for 10 days. After 3 weeks, haematologic parameters were normal. After 6 months, ASAT and ALAT were slightly elevated (55 and 75 U/l, respectively). All tests were normal by 9 months.

29.02.2004		(222)

- Type of experience** : Human
- Remark** : In a letter to the editor, the authors report a 46 yr old individual who was admitted to hospital with symptomatic wide-complex tachyarrhythmia, with subsequent diagnosis of hyperkalemia and oliguric acute renal failure and symptoms of hepatocellular necrosis, rhabdomyolysis, and a severe coagulopathy.
- Symptoms were reported shortly after having worked for 6 hours in an outdoor environment with a commercial paint fixative reported to contain 35-40% 1,2-dichloropropane and toluene (33-38%). An accidental spill resulted in gross contamination of the front part of his body, trunk and abdomen. The individual delayed removal of his clothes and skin decontamination for 5 hours suggesting probable massive dermal exposure with prolonged inhalation exposure also likely. He reported only transient redness of the involved skin areas.
- The patient responded favorably to treatment and became non-oliguric after two 10-hr sessions of dialysis over 2 d while coagulation values returned to normal over the same period. The patient was discharged after 7 d. Full renal and hepatic function recovery was demonstrated after 2 weeks.
- The authors summarize that this case represents a severe acute intoxication from 1,2-PDC via a percutaneous route of exposure, but acknowledge that additional mechanisms, which may have played a contributing role, could not be excluded.
- Reviewer's Comment:
Although the authors state that exposure is via dermal contact, given the high volatility of PDC, it is likely that inhalation of volatilized material was a major contributor to exposure during the 5-hour period while he was wearing his "drenched" shirt.

- Type** : Biochemical or cellular interactions
- Remark** : Test condition:
[¹⁴C]-marked 1,2-dichloropropane was dosed to female F344 rats via oral gavage in concentrations of 0.94; 7 and 255 mg/kg.

	<p>Results: Radiolabel was exhaled as CO₂ in concentration 27; 17 and 2 %. The liver was taken from the animals six hours after the application. Radioactivity measurement was 83 dpm/mg in the low dose group, 470 dpm/mg in the middle dose group and 52 dpm/mg in the high dose group. 90 - 95 % of this radioactivity was analyzed in the isolated liver-DNA. After the "acid depurination" of DNA, it was found that radioactive precursors of the nucleotide were present at biosynthesis and not during the covalent binding of radioactive 1,2-dichloropropane on DNA.</p> <p>Maximal DNA-damage, given as the covalent binding index (CBI = mmol of substance bound per mol nucleotide/mmol substance applied per kg body weight), was < 2 for the low dose group, < 1 for the middle dose group and < 0.3 for the high dose group.</p> <p>It can be assumed there is no strong (if existing) genotoxic risk in-vivo for 1,2-dichloropropane, as a large database already exists.</p>

Reliability	: (4) not assignable Not assignable; Insufficient detail in the IUCLID entry to determine reliability.	
26.10.2004		(225)
Type	: Biochemical or cellular interactions	
Remark	: Test condition: Two female F344 rats were inhalational exposed to radioactive [¹⁴ C]-1,2-dichloropropane resulting in intake of 25 and 27 mg/kg.	
	<p>Results: The substance was exhaled for 7 and 7.5 hours as 18 % and 14 % CO₂. At the end of the test, the animal livers were taken and DNA was isolated. Specific radioactivity in DNA was 350 dpm/mg. The separation of the DNA in natural nucleotides showed that the radioactivity is caused when the precursors were added to DNA during biosynthesis. The DNA-adducts can only be less than 3.1 % of the radioactivity in DNA. The covalent binding index CBI was given as < 0.7. This maximum possible CBI classifies 1,2-dichloropropane as 10000 times below the genotoxic potential of aflatoxin B1. A binding on DNA as an important mechanism of carcinogenic effect of 1,2-dichloropropane is improbable.</p>

Type	: Cytotoxicity	
Remark	: Method: In this study we have investigated the effects of DCP on intracellular glutathione (GSH) content in main target tissues of male Wistar rats, i.e. liver, kidney and blood, in order to establish if a correlation between DCP-induced GSH depletion and tissue damage exists. Results: Administration of DCP (2 ml/kg body weight, orally) caused a dramatic loss of tissue GSH occurring 24 h after DCP intoxication, followed by a slow restoration approaching physiological levels after 96 h. GSH depletion was associated with a marked increase in serum GOT, GPT, 5'-nucleotidase, gamma-glutamyl transpeptidase, alkaline phosphatase, urea and creatinine, and a significant decrease of hemolysis. When animals were pretreated with a GSH depleting agent, buthionine-sulfoximine (BSO; 0.5 mg/kg body weight; i.p.) 4 hours before DCP intoxication, an increase of overall mortality was found, significantly different from the group of animals treated only with DCP. On the contrary, the administration of a GSH precursor, N-acetylcysteine (NAC) i.p. (250 mg/kg b.w.) 2 and 16 hours after DCP intoxication prevented the dramatic loss of cellular GSH and reduced the extent of injury in target tissues, as demonstrated by laboratory indices. Furthermore, statistical analysis of the data revealed a correlation between: 1) depletion of liver GSH and increase in serum GOT, GPT, 5'-nucleotidase 2) depletion of kidney GSH and increase in serum urea and creatinine and 3) depletion of blood GSH and the occurrence of hemolysis.	

		The findings demonstrate that GSH plays a critical role in modulating the toxicity of DCP. They also highlight the protective role of NAC and suggest that this glutathione precursor could rationally be used in DCP poisoning in humans.

5. Toxicity

Id 78-87-5

Date 14.12.2004

Remark	: Urine and feces of F344 rats (4 animals/sex/concentration) were collected for 48 hours after inhalational exposure (head only) for 6 hours to 24, 235 and 470 mg [14C]1,2-dichloropropane/m3. 55 - 65 % of the recovered radioactivity was detected in urine and 6.3 - 9.7 % was detected in feces; 16 - 23 % of the radioactivity was exhaled as CO ₂ .	
Source Reliability	: The 1,2-Dichloropropane ICCA/HPV Consortium : (4) not assignable Not assignable; Insufficient detail in the IUCLID entry to determine reliability.	
26.10.2004		(231)
Type	: Metabolism	
Remark	: The main metabolites of 1,2-dichloropropane were identified in urine of Sprague-Dawley and F344 rats. Metabolites were N-acetyl-S-(2-hydroxypropyl)-L-cysteine, N-acetyl-S-(2-oxopropyl)-L-cysteine and N-acetyl-S-(1-carboxyethyl)-L-cysteine. A quantitative analysis showed that approximately 25 - 30 % of a single oral administration of 100 mg 1,2-dichloropropane/kg body weight was conjugated with glutathione in Sprague-Dawley rats which produced mercapturic acid derivative N-acetyl-S-(2-hydroxypropyl)-L-cysteine. The urine of F344 rats was analyzed after the administration of 100 mg /kg body weight and 10.2 % of the administered dose was recovered as N-acetyl-S-(2-hydroxypropyl)-L-cysteine, 14.5 % as N-acetyl-S-(2-oxopropyl)-L-cysteine and 1.8 % as N-acetyl-S-(1-carboxyethyl)-L-cysteine was found.	
Source Reliability	: The 1,2-Dichloropropane ICCA/HPV Consortium : (4) not assignable Not assignable; Insufficient detail in the IUCLID entry to determine reliability.	
26.10.2004		(232) (233) (231)
Type	: Metabolism	
Remark	: During the oxidation of 1,2-dichloropropane (either before or after the conjugation with glutathione), the buildup of N-acetyl-S-(1-carboxyethyl)-L-cysteine and N-acetyl-S-(2-oxopropyl)-L-cysteine appeared. The later product can be further reduced to N-acetyl-S-(2-hydroxypropyl)-L-cysteine. The process of 1,2-dichloropropane oxidation to lactate creates CO ₂ and acetyl-CoA accumulation, which is either exhaled or enters the citric acid cycle, respectively. It is shown that 1,2-dichloropropane can also be exhaled unchanged. 61 - 87 % of the exhaled radioactivity was identified as 1,2-dichloropropane, independent of administration route (inhalational or orally). Sex and administration route had no effect on the metabolism.	
Source Reliability	: The 1,2-Dichloropropane ICCA/HPV Consortium : (4) not assignable Not assignable; Insufficient detail in the IUCLID entry to determine reliability.

26.10.2004		(235)
Type	: other: Resorption	
Remark	: The highest levels of 1,2-dichloropropane in blood were detected 30 -60 minutes after the administration of 55 - 440 mg 1,2-dichloropropane/kg body weight in male Wistar rats (5 animals/dose group). The half-life of 1,2-dichloropropane in blood was 3.1 - 5.0 hours after the administration of 55 - 220 mg/kg. After the administration of 440 mg/kg, the maximal blood level was reached after only 2 hours. The half-life for 1,2-dichloropropane in blood was then 13.6 hours .	
Source	: The 1,2-Dichloropropane ICCA/HPV Consortium	
Reliability	: (4) not assignable	
26.10.2004		(217)
Remark	: In addition to N-acetyl-S-(2-hydroxypropyl)cysteine, in the study on metabolism of 1,2-dichloropropane, two other metabolites were found in urine of Sprague-Dawley rats. They were identified as N-acetyl-S-(2,3-dihydroxypropyl)cysteine and beta -chlorolacate. The presumption would be that metabolism of 1,2-dichloropropane to N-acetyl-S-(2-hydroxypropyl)cysteine follows a dechlorination and oxidation step to 1-chloro-2-hydroxypropane. Further dechlorination produces N-acetyl-S-(2-hydroxypropyl)cysteine. Analysis of urine showed two substances beta -chlorolactate and S-(2,3-dihydroxypropyl)cysteine, which could have originated from 1-chloro-2-hydroxypropane.
